SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 421, Reston, VA 22092, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are:
Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 17, NUMBER 1
JANUARY 1984

W84-00001 -- W84-00350

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Office of Management ond Budget through September 30, 1985.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

7/1-6

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientitsts, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

A METHOD FOR CALCULATING THE RATE OF BIOSEDIMENTATION THROUGH THE LOWER BOUNDARY OF THE PHOTOSYNTHETIC ZONE IN SEA WATER,
Institute of Biology of the Southern Seas, Sevastopol (USSR).
V. N. Yegorov, V. N. Ivanov, and L. V. Migal.
Hydrobiological Journal, Vol 17, No 4, p 69-74, 1981. 3 Fig, 15 Ref.

Descriptors: *Sea water, *Biosedimentation, Sedimentation, Photosynthesis, Vertical flow, Vertical distribution, Water chemistry, Uranium-238, Thorium-234, *Indian Ocean.

An attempt was made to calculate the rate of water exchange in the euphotic layer on the basis of data about its productivity and on the vertical distribution of various forms of zinc. Use was made of the balance equations for zinc and Th-234 to analyze both the rate of biosedimentation and the velocity of water exchange in the euphotic layer. Studies were based on data from a test area in the Indian Ocean. The rate of water exchange through the lower boundary of the photosynthetic zone and the biosedimentation potential of the euphotic layer could be calculated on the basis of simultaneous observations of the vertical distribution of a trace element (zinc) and the shift in the equilibrium concentrations of uranium 238 and thorium 234. The errors of the method are discussed. (Baker-FRC)

HYDROLOGY OF A SMALL IMPOUNDMENT AND WATERSHED IN CENTRAL OKLAHOMA,
Agricultural Research Service, Chickasha, OK.
R. Schoof.
Water Resources Bulletin, Vol 19, No 1, p 15-21, February, 1983. 4 Fig, 6 Tab, 9 Ref.

Descriptors: *Watershed, *Impoundments, *Hydrology, *Oklahoma, Runoff, Rainfall-runoff relationships, Evapotranspiration, Evaporation, Bitter Creek.

An analysis is presented of a site impoundment's water budget for five years of record, along with a study of the temporal and spatial distribution of water yield from the contributing watershed, measured from 1972 through 1980. On-site loss of water from the impoundment was only 17% of the inflow during three years when the annual precipitation averaged 26 inches and the annual inflow averaged 1.4 inches. Runoff from an eroded area with no farm ponds was about 70% greater per unit area than from a portion of watershed where 71% of the drainage area was controlled by farm ponds. Loss of top soil increased runoff significantly. Only 24% of the total runoff into the impoundment was base flow. The flow rate into the impoundment was less than 0.05 cfs 70% of the time, and the inflow rate exceeded 10 cfs only 1% of the time. SCS runoff curve numbers varied between 57 and 96 for the impoundment watershed, with an inverse relation between precipitation amount and curve number, apparently caused by partial area runoff from impervious and semi-impervious areas. A comparison of measured event runoff computed by the SCS curve numbers gave an r sq of only 0.44. However, the total computed surface runoff for eight years of record was less than 1% below the measured runoff, which indicated that the curve number method was a good tool for predicting long term runoff for the watershed. (Baker-FRC)

CONSTANT VELOCITY KINEMATIC ANALYSIS OF AN INFILTRATING MICROCATCHMENT HYDROGRAPH,
Ben-Gurion Univ. of the Negev, Sde Boker (Israel). Jacob Blaustein Inst. for Desert Research.
Y. Zarmi, J. Ben Asher, and T. Greengard.
Water Resources Research, Vol 19, No 1, p 277-283, February, 1983. 3 Fig, 2 Tab, 17 Ref.

Descriptors: *Infiltration, *Surface flow, *Water harvesting, Arid lands, Hydrodynamics, Rainfall intensity, Hydrographs, Flow patterns, Overland flow, Flow velocity, Soil properties, Runoff.

This paper describes the development and testing of a physical model to predict the hydrodynamic processes on a natural microcatchment of about 200 sq m, which is the size needed in arid zones for providing irrigation water for one tree. Rainfall was applied to a 125 sq m catchment with a fairly uniform grade of 1%. The recession parts of the hydrographs were similar for rainfall intensities of 60, 40, 20, and 10 mm per hour. Recession lasted about 10 min and was independent of the surface detention. Recession limbs of the hydrographs decreased very rapidly the moment the rain stopped and appeared as a series of parallel, nearly perpendicular lines on the discharge vs. time plot. It was possible to assume that the velocity of water flow on the surface was constant, independent of time or position along the catchment. This allowed the analytical solution of the continuity equation to be simplified, providing better insight into the problem of surface flow. (Cassar-FRC)

RUNOFF MODEL FOR WATERSHEDS OF NONHOMOGENEOUS HYDROLOGIC CHARACTERISTICS,
New Mexico Univ., Albuquerque. Dept. of Civil Engineering.
R. J. Heggen.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113596, Price codes: A07 in paper copy, A01 in microfiche.
New Mexico Water Resources Research Institute Technical Report No. 176, Las Cruces, September 1983. 136 p, 11 Fig, 6 Tab, 54 Ref, 5 Append.
OWRT A-068-NMEX(1), 14-34-0001-2133.

Descriptors: *Small watersheds, *Hydrologic models, Runoff, Watershed studies, *Flood routing, Water yield, Infiltration, *Watershed models, Model studies, New Mexico, Four Hills watershed, North Camino watershed.

A Watershed of any configuration, topography, spatial distribution of cover and soil, and channel characteristics is described as non-homogeneous finite-element surface grid. Time-varying precipitation is applied to the watershed and runoff is hydraulically routed over the surface in discrete time increments. Infiltration is abstracted by a variable rate model derived from SCS curve numbers. Precipitation infiltrates, stands, and/or runs off each quadrant in accordance with that quadrant's slope and hydrologic characteristics. Overland flow is routed to channels, and channel flow is then routed to the basin's point of discharge. The grid definition of the watershed surface makes the model appropriate for watershed not adequately modeled by conventional, nondistributed hydrologic means. The model does not require that unit hydrographs or times-of-concentration be estimated.

HYDROGEOLOGY (HYDROGEOLOGIE),
Centre National de la Recherche Scientifique, Moulis (France). Lab. Souterrain.
A. Mangin.
Comptes Rendus Hebdomadaires des Seances de l'Academie des Sciences, Serie 2: Mecanique-Physique, Vol 293, No 14, p 1011-1014, 1981. 3 Fig, 8 Ref.

Descriptors: *Hydrographs, *Hydrograph analysis, Discharge hydrographs, Rainfall, Simulation analysis, Mathematical studies.

The application of cross correlation and cross spectral analysis to rainfall and discharge time series leads to a better hydrological system identification through improved results from unit hydrographs, their analysis with respect to the functioning of the hydrological systems, and quantitative estimation of source parameters, such as linearity. These factors constitute a valuable step for the investigation of system simulation. (Author's abstract)

TRENDS IN THE VARIATION OF SURFACE WATERS OF THE HYDROSPHERE,
R. K. Klige.
Water Resources (English Translation), Vol 9, No 3, p 272-284, May-June, 1982. 5 Fig, 4 Tab, 40 Ref. Translated from Vodnye Resursy, No 3, p 92-105, May-June, 1982.

Descriptors: *Surface water, *Temperature effects, *Water exchange, *Water resources, World ocean, Evaporation, Global water, Hydrosphere, Geohydrology, Groundwater hydrology, Water levels.

In order to correctly understand current changes and trends in surface waters of the hydrosphere a determination was made of the processes of evolution of natural waters that led to their present state. In this connection the paleohydrologic conditions for individual successive time segments were reconstructed. Specific time periods included the earth's early stages of geologic history, Early Makhachkala, Shikhova, Late Makhachkala, Begdash, Sartas, Julala, Dagestan, Zhelanda, Gousan, Izberbash, Turala, Aleksandrbai, Uluchaevo, Abeskun, the late history and the present time. The very early stages of earth's geologic history were also included along with the Phanerozoic period and the late Paleozoic period. An investigation of global water-exchange processes shows that under the existing climatic conditions and in the future a directed change in the components of the water balance of the earth's surface will occur as a result of which land water supplies will be reduced by about 133 cubic km/yr and the volume of glaciers by 183 cubic km/yr with further replenishment of the World Ocean at a rate of 316 cubic km/yr. Modeling of changes in the conditions of global water exchange are considered for temperature changes of 1 and 2.5 degrees. (Baker-FRC)
W84-00316

WATER BALANCE OF THE BLACK SEA IN THE LATE VALDAI GLACIAL EPOCH,
Moscow State Univ. (USSR).
S. I. Varushchenko.
Water Resources (English translation), Vol 9, No 3, p 311-313, May-June, 1982. 2 Tab, 11 Ref. Translated from Vodnye Resursy, No 3, p 136-138, May-June, 1982.

Descriptors: *Water resources, *Water balance, *Geohydrology, Hydrosphere, Water exchange, Glaciers, Europe, USSR, Don River, Danube River, Dnestr River, Dnepr River, Black Sea.

On the basis of the bathygraphic curve, the areas and volumes of water are calculated for the Black Sea for two levels: the early maximum level of the Bosporus sill (-35 m) and the surface corresponding to the present day 95-m depth of the sea. The first level, having an area of about 402,000 sq km,

dates to the epochs of detachment and subsequent joining of the water body to the Mediterranean Sea, and the second, having an area of about 367,000 sq km, corresponds to the average level of development of the deepest New Euxine lake terraces of those expressed in the bottom relief. The data presented permit an approximate determination of how much the mean annual runoff to the New Euxine Lake decreased in the time interval from 29,000 to 9000 years ago compared to the present runoff to the Black Sea. Since from 85 to 90% of the surface waters in the New Euxine Lake came from rivers emptying into it from the north, it is concluded that the main cause of the drop of the level of this water body after its detachment from the ocean was the abrupt and very substantial reduction of the volume of river runoff from the periglacial region of the glacier during its occurrence and stabilization in the maximum phase of development. In the initial and final stages of development of the glacier the runoff was about two times and at the maximum possibly even twelve times less than the present day. The data indicate that during the last glaciation the basins of the Danube, Dnestr, Dnepr, and Don were in a zone of quite feeble moistening. The calculations indicate an exceptionally dry climate in the area and indirectly confirm the possibility of the wide develelopment of tundra steppes in the indicated period in southern Europe. (Baker-FRC)

THE HYDROLOGICAL SUSA-STUDY,
Technical Univ. of Denmark, Lyngby. Inst. of Hydrodynamics and Hydraulic Engineering.
E. Hansen, and M. Dyhr-Nielsen.
Nordic Hydrology, Vol 13, No 5, p 257-262, 1982. 2 Fig.

Descriptors: *Rainfall-runoff relationships, *Model studies, Hydrologic models, Denmark, Hydrology.

A short description is offered of a 4.5 year hydrological research project constituting a Danish contributon to UNESCO's International Hydrological Program. The main objectives of the project were to study the hydrologic processes in a catchment with a regional confined aquifer covered by boulder clay; the consequences of increased ground water development on groundwater hydraulic heads and streamflow; the possibilities of establishing an integrated water resources development, taking into account joint effects of water abstraction and sewage disposal on the water quantity and quality of the streams in the catchment. Field studies of hydrological processes were conducted for precipitation, evapotranspiration, subsurface runoff, groundwater recharge, hydrogeology, interaction between groundwater and surface water, runoff and lake storage, and chemistry of ground- and surface water. Mathematical modeling of hydrological processes and systems were constructed for evapotranspiration, groundwater, rainfall-runoff, and integrated hydrologic models. (Baker-FRC)
W84-00338

ESTIMATION OF THE VOLUME OF REGENERATED WATER OF THE CONTINENTAL CRUST IN GLOBAL WATER EXCHANGE,
O. M. Rozen.
Water Resources (English Translation), Vol 9, No 3, p 285-297, May-June, 1982. 4 Fig, 6 Tab, 50 Ref. Translated from Vodnye Resursy, No 3, p 106-118, May-June, 1982.

Descriptors: *Water exchange, *Water resources, *Hydrosphere, *Geohydrology, World Ocean, Paleohydrology.

An attempt has been made to estimate the balance of buried water and water released from volcanogenic-sedimentary rocks during the formation of the earth's crust. The examination of the indicated balance was limited to only two principal forms of burial of water: first, water present in the crystal lattice of minerals of sedimentary rocks and amenable to a theoretical quantitative estimation, and second, water filling the pores of sedimentary rocks and which is to a considerable extent relict and syngenetic, a quantitative estimation of which can be made on the basis of the data on the total porosity of sedimentary rocks. The data obtained show that during the formation of both the lower and upper horizons of the continental crust vast amounts of water were buried, which are quite close to those calculated for interstitial waters of nonmetamorphosed deposits and equal to about 20% of the entire hydrosphere. They exceed by an order of 1.5 the mass of ice, rivers, lakes, and water in the atmosphere taken together. The amount of water buried in rocks during the entire history of the earth amounts to 60% of the entire hydrosphere. The release of such masses of water led to a change in the volume of the World Ocean. For estimating such a flow of water it is assumed that it occurred in each of the principal epochs of metamorphism and granitization in the Precambrian period. Bulging up of granitoids and orogeny, leading to the geologically instantaneous supply of a large amount of terrigenous material to the ocean, are an important accompanying consequence of global epochs of metamorphism. The combination of an increase in the volume of water and its displacement by the incoming terrigenous sediments should have led to an increase of its level and to transgressions. The periodic rises of the World Ocean level were probably originally quite intense, gradually decreasing in intensity with the passage of time. (Baker-FRC)
W84-00345

INTERRELATIONSHIP BETWEEN RELIEF, GLOBAL CLIMATE, AND WATER EXCHANGE,
L. V. Zorin.
Water Resources (English Translation), Vol 9, No 3, p 329-334, May-June, 1982. 44 Ref. Translated from Vodnye Resursy, No 3, p 156-161, May-June, 1982.

Descriptors: *Water exchange, *Geohydrology, *Water resources, World Ocean, Temperature effects, Climate, Water balance, Hydrosphere, Advection, Convection.

The effect of the relief on global climate and water exchange is investigated. Along with the paleogeographic aspect the present day aspect of the relation between continental relief and water balance is considered. It is noted that the amount of solar energy received by the earth periodically changed to extents which caused fluctuations of the climate and water exchange and the occurrence of glaciation and pergelation. Variations of the climate and water exchange, having a periodic large-scale character, were related mainly to the geotectonic evolution of the earth. There are direct indications that glaciation on the earth actively degrades; having reached a maximum in the Middle Pleistocene, it expanded in surges but on a considerably smaller scale in the Upper Pleistocene and in the Little Ice Age. Presently global glaciation is decreasing, which is displayed in unstable melting of present-day glaciers of both the mountain and, in part, flatland types and also of permafrost. It is concluded that the more complex the relief, the more complex the processes of advection and the more active the processes of convection. More complex reliefs also call for greater complexity in the circulation processes and for a more complicated process of large-scale condensation occurring on land. In epochs of plantation and denudation of mountains, that is, in epochs of cessation or slowing of global expansion, equalization of the climate will occur, accompanied by melting not only of mountain glaciers but also of the polar ice caps. The climate will become ordered, and water exchange will stabilize, with natural waters concentrating in the oceans. (Baker-FRC)

CHEMICAL COMPOSITION AND SPATIAL VARIATION OF BULK PRECIPITATION AT A COASTAL PLAIN WATERSHED IN SOUTH CAROLINA,
Duke Univ., Durham, NC. School of Forestry and Environmental Studies.
D. D. Richter, C. W. Ralston, and W. R. Harms.
Water Resources Research, Vol 19, No 1, p 134-140, February, 1983. 4 Fig, 3 Tab, 37 Ref.

Descriptors: *Precipitation, *Spatial variation, *Chemical composition, Water pollution sources, Fate of pollutants, *South Carolina, Phosphates, Sulfates, Nitrates, Ammonium, Hydrogen ion concentration, Rain, Chlorides, Potassium, Sodium, Magnesium, Calcium, Forest watersheds, Nutrients.

Ionic constituents of rain water were determined in samples from 8 stations in a 500-ha watershed in the Francis Marion National Forest, located in the coastal plain of South Carolina. Mean annual deposition rates of ions (kg per ha) were: H+, 0.64; Ca(++), 5.69; Na+, 5.66; Mg(++), 1.68; ammonium-N, 0.83; K+, 0.94; sulfate-S, 7.51; chloride, 14.2; nitrate-N, 1.76; and phosphate-P, 0.12. Spatial variations were < 10% for sulfate-S, nitrate-N, and Ca(++); intermediate for Mg(++), chloride, H+, and Na+; and 30-35% for ammonium-N, phosphate-P, and K+. Sources of the various constituents were oceanic salts, fossil fuel combustion, natural biogenic processes, agricultural activities, and soil-derived particulates. For this watershed 19 sample collectors would be sufficient to estimate annual bulk precipitation inputs within 10% of true mean for sulfate, nitrate, Ca(++), Mg(++), chloride, H+, and Na+, whereas 35 collectors would be required to provide similar confidence intervals for ammonium, phosphate, and K+. (Cassar-FRC)
W84-00108

A POINT PROCESS MODEL OF SUMMER SEASON RAINFALL OCCURRENCES,
Interstate Commission on the Potomac River Basin, Rockville, MD.
J. A. Smith, and A. F. Karr.
Water Resources Research, Vol 19, No 1, p 95-103, February, 1983. 24 Ref.

Descriptors: *Rainfall, *Drought, *Cluster analysis, Model studies, Seasonal variation, Precipitation, Potomac River Basin, Meteorology, Stochastic hydrology, *Model studies, *RCM processes.

A point process model of summer season rainfall occurrences is developed. The model, which is termed an RCM process (renewal Cox process with Markovian intensity), is a member of the family of Cox processes (Poisson processes for which the rate of occurrence of events varies randomly over time). Model development is based on counts and interarrival time statistics estimated from Potomac River basin rainfall data. The counting parameters used are the conditional intensity function, index of dispersion and counts spectrum; the interarrival time parameters are the coefficient of variation and the autocorrelation function. Explicit results are presented for the counts and interarrival time parameters of RCM processes. For the RCM process the rate of occurrence alternates between two states, one of which is 0, the other positive. The form of the intensity process suggests that clustering of summer season rainfall occurrences in the Potomac River basin results form the alternation of wet and dry periods. Computational results are presented for two extensions of the RCM process model of rainfall occurrences: a marked RCM process model of rainfall occurrences and associated storm depths and a bivariate RCM process model of rainfall occurrences at two sites. (Author's abstract)
W84-00117

A SIMPLE PROCEDURE FOR CALCULATING ATMOSPHERIC WATER VAPOR CONCENTRATION,
California Inst. of Tech., Pasadena.
G. J. McRae.
Journal of the Air Pollution Control Association, Vol 30, No 4, p 394, April, 1980. 2 Ref.

Descriptors: *Water vapor, *Mathematical equations, *Relative humidity, Mathematical studies, Air temperature, Atmospheric pressure.

A simple procedure, accurate to 0.5% over a range of plus or minus 50 degrees, is presented for calculating water vapor concentration without the use

of psychrometric charts or tables. The mathematical equation which equates relative humidity to the ratio of the mole fraction of water vapor in the moist atmosphere to the mole fraction at saturation is rewritten using Dalton's gas laws and Richards' polynomial expression. The resultant expression allows the determination of water vapor concentration in parts per million units or in other unit systems by straightforward conversion. (Geiger-FRC)
W84-00304

METHODS FOR CALCULATING AREAL PRECIPITATION - APPLIED TO THE SUSA-CATCHMENT,
Danish Meteorological Inst., Copenhagen.
P. Allerup, H. Madsen, and J. Riis.
Nordic Hydrology, Vol 13, No 5, p 263-278, 1982. 18 Fig, 1 Tab, 13 Ref.

Descriptors: *Rainfall distribution, *Terrain analysis, *Wind, Susa catchment, Catchment areas, Hills, Rainfall, Distribution, Topography.

In order to study the influence of the terrain on the precipitation pattern in the Susa catchment, a separate raingauge setup was established in two hilly areas. Before calculation of real precipitation could be carried out, correction of precipitation due to systematic errors was needed. A special method, the TTSE method, was developed to take into account the terrain characteristics. The Susa catchment is characterized by a gently undulating landscape surrounding the Susa and its tributaries. Ranges of hills rise 20-30 m above the surrounding landscape in some areas and 80-90 m in others. A statistical model study was carried out to analyze the data collected from the raingauge network. It appeared from the study that both the existence of small hills and the direction of the wind influence the amount of precipitation a given area will receive. (Baker-FRC)

ICE BREAKUP AND JAMMING OBSERVATIONS ALONG THE MACKENZIE RIVER,
Queen's Univ., Kingston (Ontario). Dept. of Civil Engineering.
J. W. Kamphuis, and J. R. Moir.
Canadian Journal of Civil Engineering, Vol 10, No 1, p 78-91, 1983. 14 Fig, 1 Tab, 2 Ref.

Descriptors: *Ice breakup, *Ice jams, *River flow, Floating ice, Mackenzie River, Melting.

Ice breakup in the northerly flowing Mackenzie River, Canada, between Forts Simpson and Good Hope was studied in 1979-1981. This paper reports the observations made from 40 aircraft flights in 1980-81. Shortly before initial downstream movement of the ice open water is seen around islands, along main shores, over shoals, and in shallow secondary channels, with remnants of shorefast ice in the apparently open water areas. In deep straight reaches the river is almost entirely covered with a solid floating ice sheet. Ice begins to move downstream when the forces keeping the ice in place are exceeded by the driving forces (gravity, shear stress on the bottom of the ice, and form drag by the flow on the ice sheet). Ice movement begins in the shallow, braided sections, forming a mush of relatively small pieces with some larger flows. Moving downstream, the mush encounters more solid ice in the straight stretches, pushing on it until the sheet moves as a unit for up to 1 km. Thickening occurs in the downstream section of the mush and along the shores. Several jams, separated by open water, appear in a river simultaneously. Release of the jam may occur by movement of the whole ice mass or by downstream movement of the mush through failures in the solid ice sheet or under the ice sheet. Breakup, rate of breakup, and jam clearing are dependent on the strength of the ice, air temperature, and wind velocity. (Cassar-FRC)

Descriptors: *Evaporation, *Evaporation Rate, *Cooling ponds, *Waste heat, *Convection, Water loss, Water consumption, Lakes, Thermal pollution.

Cooling ponds have been routinely utilized for the dissipation of industrial waste heat. A by-product of this application is an increase in evaporative losses over the naturally occurring value. The present study describes some analyses of this evaporation and means to measure and/or calculate it. Mathematical models using an energy budget approach are shown to be least sensitive to errors in the wind speed function. The second portion of the study examines the relative effects of evaporation resulting from free convection (zero windspeed) and forced convection. A new evaporation equation for heated and nonheated lakes is presented.

IMPACT OF DROUGHT ON QUALITY OF POTENTIAL WATER SUPPLY SOURCES IN THE SANGAMON RIVER BASIN,
Southern Illinois Univ. at Carbondale. Dept. of Thermal and Environmental Engineering.
C. B. Muchmore, and B. Dziegielewski.
Water Resources Bulletin, Vol 19, No 1, p 37-46, February, 1983. 6 Fig, 5 Tab, 10 Ref.

Descriptors: *Water quality, *Drought, *Water supply, Water resources development, Ammonia, Manganese, Phenols, Specific conductance, Rivers, River basins, Streamflow, *Illinois, Sangamon River basin.

An analysis was made of streamflow and several water quality parameters in six Illinois rivers. The analysis showed that the 1976-77 drought produced significant streamflow deficiencies in the investigated streams of the 5,000 sq mile basin of the Sangamon River. Temporal and spatial variability of precipitation deficits within the basin had insignificant effects on the differentiation in timing of extremely low flows among various streams. The impact of drought on water quality was less uniform than the impact on streamflow. Overall, streamflow quality deteriorated, as a result of abnormally high concentrations of ammonia, maganese, and to a lesser extent, phenol and specific conductance. Significant decreases in concentrations of nitrites and nitrates, coliform bacteria, and total iron were noted. The approach to the analysis of water quality, using 12-month moving averages of monthly quality measurements, proved to be sensitive enough to clearly isolate the impact of drought from seasonal fluctuations in water quality. The analysis of instream flow and moving averages of nitrogen species concentrations revealed two distinct patterns of response to drought. They corresponded to streams chararcterized by an alternately high or low contribution of treated municipal effluent to low flow. The effects of land use patterns on water quality during the drought were hard to isolate due to the relative similarity of land uses for all investigated subbasins. However, the more general thesis regarding the significant differences in response to drought among various streams seems to be substantiated in the case of impacts on water quality. It is suggested that streams which are considered unsuitable for municipal supply due to high levels of the quality indicators studied may be used as emergency sources during droughts. (Baker-FRC)

EXTREMAL HYPOTHESES FOR RIVER BEHAVIOR,
Canterbury Univ., Christchurch (New Zealand). Dept. of Agricultural Engineering.
T. R. H. Davies, and A. J. Sutherland.
Water Resources Research, Vol 19, No 1, p 141-148, February, 1983. 2 Fig, 1 Tab, 38 Ref.

Descriptors: *Energy dissipation, *River flow, *Friction, Streamflow, Turbulent flow, Laminar flow, Alluvial rivers, Minimization hypotheses, Sediment transport.

The hypotheses of minimum energy dissipation, minimum stream power, and minimum unit stream power are summarized and compared. Their derivation from analogies with laminar flow and linear thermodynamics is criticized on the grounds that these situations differ fundamentally from river flows, which are usually highly turbulent and strongly nonlinear. The authors' empirical hypothesis of maximum friction factor seems preferable to the minimization hypotheses because it is compatible with the known behavior of turbulent flows and nonlinear processes, it is applicable with a wider range of independent variables, and it is more in keeping with trends shown by experimental data under all constraints. The minimization hypotheses seem likely to give incorrect predictions when flow rate and depth are independent variables. The empirical success of the minimization hypotheses is confined to situations in which they predict similar behavior to the maximum friction factor hypothesis; they may be considered as special cases of this more general hypothesis. (Author's abstract)

A TIME DEPENDENT, TWO-LAYER FRONTAL MODEL OF BUOYANT PLUME DYNAMICS,
Delaware Univ., Newark. Coll. of Marine Studies.
J. O'Donnell, and R. W. Garvine.
Tellus, Vol 35A, No 1, p 73-80, 1983. 7 Fig, 19 Ref.

Descriptors: *Mathematical equations, *Plumes, *Buoyancy, Mississippi River, Connecticut River, Rivers, Dynamics.

The one-dimensional, time dependent behavior of a two-layer frontal model is considered in a study of the dynamics of buoyant plumes such as those observed at the mouths of the Mississippi and Connecticut Rivers. The long wave equations are solved numerically with several different boundary conditions in order to illustrate some of the properties of the model. The results of the four numerical experiments performed demonstrated that the frontal motion of buoyant plumes is strongly controlled by the flow at the inlet. Control is exerted by the generation of internal waves which propagate toward the front, where they modify the flow. If changes in the inlet flow occur with short time scales, then these internal waves can develop into surges or bores which would effectively increase the amount of interfacial mixing. These results, together with those of Garvine, encourage the extension of this model and its numerical solution technique to two horizontal dimensions in order to more closely approximate the behavior of natural buoyant plumes. COMMENT ON 'OPTIMAL RISK-BASED DESIGN OF FLOOD LEVEE SYSTEMS' BY Y.-K. TUNG AND L. W. MAYS,
Tiszadata Consulting Engineers, Budapest (Hungary).
I. Bogardi, and L. Duckstein.

Water Resources Research, Vol 18, No 6, p 1745-1746, December, 1982. 6 Ref.

Descriptors: *Levees, *Flood routing, Flood protection, Optimization, Design criteria, Dynamic programming.

A comment on the above titled paper, published in Water Resources Research, Volume 17, No 4, pages 843-852, 1981, states that the assumption that no routing techniques are applied to route the flood hydrography through the levee system does not take into account the observation that flooding in an upstream reach decreases the peak stage in the downstream reaches. Closed loop methods are proposed as alternatives to this open loop method. (Cassar-FRC)

AN EIGENVALUE NUMERICAL TECHNIQUE FOR SOLVING UNSTEADY LINEAR GROUNDWATER MODELS CONTINUOUSLY IN TIME,
Servicio Geologico de Obras Publicas, Madrid (Spain).
A. Sahuquillo.
Water Resources Research, Vol 19, No 1, p 87-93, February, 1983. 14 Ref.

Descriptors: *Groundwater management, *Groundwater movement, *Aquifers, Differential equations, Eigenvalues, Numerical analysis, Piezometric head, Leaky aquifers, Confined aquifers, Pumping.

A procedure is presented for solving the differential groundwater flow equation. Using a finite difference or finite element discretization scheme, a set of simultaneous linear equations is obtained. The eigenvalues and eigenvectors of a matrix, which is a function of the coefficients of the set, are the key to the solution. A vector (L) is obtained straightforwardly by combining the eigenvector matrix (A), the eigenvalue vector, the pumping vector (P), and the initial head vector. Vector L, which depends on time, can be expressed simply and explicitly as a function of the eigenvalues. Piezometric heads can be obtained by combining A and L. L is the only vector that needs to be computed as P changes with time. In this way, influence functions of a piezometric head, flow velocity, and flow depletion of a stream connected with the aquifer under a unit stress can be obtained explicitly and continuously in time. The method can be applied to confined as well as to leaky aquifers and to one-, two-, or three-dimensional linear models. Its main advantage lies in the fact that it is unnecessary to repeatedly solve a matrix for every time increment. The method is particularly useful for groundwater management problems in which a large number of alternatives have to be evaluated. (Author's abstract)

AQUIFER PARAMETER IDENTIFICATION WITH KRIGING AND OPTIMUM PARAMETERIZATION,
California Univ., Los Angeles. School of Engineering and Applied Science.
W. W. G. Yeh, Y. S. Yoon, and K. S. Lee.
Water Resources Research, Vol 19, No 1, p 225-233, February, 1983. 9 Fig, 4 Tab, 17 Ref.

Descriptors: *Aquifer properties, *Parametric hydrology, Groundwater movement, *Kriging.

A new parameter identification method is developed for a two-dimensional, unsteady state groundwater flow model. The method is a direct approach, as it requires no iterative searching of parameters. The unknown functional coefficients (parameters) are optimally determined by a generalized matrix inversion scheme. Kriging, an unbiased minimum variance estimator, is used as a presampling filter to reconstruct the head distribution for the entire flow domain. The ill-posedness of the inverse problem as characterized by instability and nonuniqueness is controlled by reparameterization utilizing the technique of finite elements. A set of statistics was developed to quantify explicity the tradeoff between the system modeling error and the error associated with the parameter uncertainty. These two types of errors were shown to be a function of the parameter dimension. Residual mean square and trace of the covariance matrix of the estimated parameters served as good indicators for the determination of the optimum parameter dimension. A set of numerical experiments was conducted to illustrate the methodology. (Author's abstract)

HEAT TRANSFER IN FRACTURED GEOTHERMAL RESERVOIRS WITH BOILING,
California Univ., Berkeley. Lawrence Berkeley Lab.
K. Preuss.
Water Resources Research, Vol 19, No 1, p 201-208, February, 1983. 10 Fig, 1 Tab, 20 Ref.

Descriptors: *Heat transfer, *Geothermal studies, *Porous media, Geologic fractures, Enthalpy, Permeability, Injection wells.

Nonisothermal flow of water and steam in idealized fractured porous media was studied with analytical and numerical techniques. Several conclusions were reached. The behavior of fractured boiling reservoirs can be different from porous medium-type reservoirs with the same permeability and porosity, even in cases where fracture spacing is small. Heat transfer to fractures by conduction is very important if matrix permeability is low. For production without reinjection reservoir response depends more strongly upon matrix permeability than on fracture spacing. It is possible that fractured geothermal reservoirs may produce superheated steam even in the presence of large quantities of liquid water flowing in the matrix. Full reinjection can be effective for maintaining pressure in fractured reservoirs. Excellent thermal sweeps can be achieved even in cases with large fracture spacing (several hundred meters) unless major short circuits in fractures are present. (Cassar-FRC)

A NUMERICAL PROCEDURE FOR THE SOLUTION OF THE STEADY STATE VARIABLE DENSITY GROUNDWATER FLOW EQUATION,
Geological Survey, Austin, TX. Water Resources Div.
L. K. Kuiper.
Water Resources Research, Vol 19, No 1, p 234-240, February, 1983. 3 Fig, 11 Ref.

Descriptors: *Groundwater movement, *Saline water intrusion, *Spatial variation, Density, Finite difference methods, Pressure head.

A numerical code is developed for the solution to the three-dimensional steady state groundwater flow equation in which groundwater density varies with spatial position and is treated as a known spatially dependent parameter. The integrated finite difference grid elements of the numerical code are rectangular when viewed along the vertical direction, but their top and bottom surfaces parallel or are coincident with the interfaces between the geologic strata within the solution region. Conditions that are sufficient for the accuracy of the code are derived. Approximate solutions for pressure head, as determined from the code, are compared for accuracy with several exact analytic test solutions. (Author's abstract)

SIMULATION OF SALT WATER-FRESH WATER INTERFACE MOTION,
Valencia Univ. (Spain).
J. Ferrer Polo, and F. J. Ramos Ramis.
Water Resources Research, Vol 19, No 1, p 61-68, February, 1983. 6 Fig, 13 Ref.

Descriptors: *Saline water intrusion, *Groundwater movement, *Coastal aquifers, Model studies, Mathematical models, Saline-freshwater interfaces, Aquifers, Unconfined aquifers, Confined aquifers.

A mathematical model for saline water intrusion describes the salt water-fresh water motion with a sharp interface. It was used to develop a numerical model (finite difference method) which unconditionally convergent and stable. The numerical model was verified by simulating three cases for which analytical results were known. These were: (1) steady state analytical solution (for two cases, confined and unconfined aquifer), (2) unsteady state solution with variable boundary conditions at the coast, and (3) unsteady state analytical solution including only motion of the interface tip and toe. The numerical model and analytical results agreed well for Case (1) and Case (3). In Case (2) agreement was good close to the interface tip and became less favorable toward the interface toe. THE WATER-TABLE OF THE RHINE PLAIN IN ALSACE (LA NAPPE PHREATIQUE DE LA PLAINE DU RHIN EN ALSACE),
Strasbourg-1 Univ. (France). Bureau de L'Environnement.
L. Simler.
Techniques et Sciences Municipales, No 2, p 79-88, February, 1981. 17 Fig, 1 Tab.

Descriptors: *Water table fluctuations, *Groundwater pollution, *Groundwater movement, Alluvial plains, Natural water table, Water table profiles, France, Rhine River, Alsace.

The water table of the Rhine Plain in Alsace, France, is contained in a lamellar alluvion system, which fortunately behaves like a large-scale homogeneous medium. Transmissivity depends only on the thickness of the alluvium. Moreover, the effects of the slow circulation of groundwater and of the rapid displacement of water in the fluvial system interfere with the action of the water table. The water table levels are thus autoregulated, especially since the fluvial system is dense. These interference phenomena explain the mechanisms of pollution, and notably of pollution by chlorides, and may be used for determining the speed of pollution removal when pollution sources are eliminated. SIMPLE METHOD FOR PREDICTING DRAINAGE FROM FIELD PLOTS,
Griffith Univ., Nathan (Australia). School of Australian Environmental Studies.
J. Y. Parlange.
Soil Science Society of America Journal, Vol 46, No 4, p 887-888, July-August, 1982. 2 Ref.

Descriptors: *Mathematical equations, *Drainage patterns, *Surface tension, *Diffusion coefficient, *Soil water suction, Model studies, Mathematical models, Drainage, Surface drainage, Prediction, Soil water.

A simple method based on analytical solutions of Sisson et al. (1980) for predicting drainage from field plots is proposed. The work of Sisson and colleagues assumes that gravity is primarily responsible for water movement during drainage and neglects the effects of diffusion. The neglect of surface tension effects may lead to significant errors near the soil surface. In the new equation,

profiles at a given time are translated upwards by gamma cm (treated as a constant), where gamma depends on suction near the surface and the time is adjusted to conserve mass. These corrections bring the analytic and numerical solutions closer together. (Geiger-FRC)

SOIL SOLUTE CONCENTRATION DISTRIBUTIONS FOR SPATIALLY VARYING PORE WATER VELOCITIES AND APPARENT DIFFUSION COEFFICIENTS,
Arizona Univ., Tucson. Dept. of Soils, Water and Engineering.
A. Amoozegar-Fard, D. R. Nielsen, and A. W. Warrick.
Soil Science Society of America Journal, Vol 46, No 1, p 3-9, January-February, 1982. 10 Fig, 1 Tab, 13 Ref.

Descriptors: *Fate of pollutants, *Soil water, *Salts, *Simulation analysis, *Spatial distribution, *Solute transport, *Monte Carlo method, *Interstitial water, Saline water, Mathematical studies, Soil porosity, Porosity, Permeability coefficient.

Knowledge of the movement of salts and other water-carried constituents through soils is important in maintaining productive agriculture and a healthy environment. A Monte Carlo simulation was performed to predict relative solute concentrations and solute movement properties as affected by the variability of pore water velocity (v) and apparent diffusion coefficient (D). Normal distribution of the natural log of v, the natural log of D, and water-filled porosity were used to determine 2,000 values of relative solute concentrations using the solute flow equation with no soil-solute interaction. Both step and pulse inputs of salt water were simulated. For pulse input, both equal depths and equal infiltration time were studied. Results showed sharp differences between the solute profiles when deterministic values of v are used compared to the average salt profile for 2,000 random values of v. The variability of D was also found to be less important than for v, especially for greater depths. For the pulse input, more salt will occur in the upper part of the profile when 7.5 cm of salt water infiltrate at each point in the field than when 7.5 cm is the average infiltration depth for the whole area. PRODUCTIVITY OF WESTERN LARCH AND SUBSOIL PERCOLATION RATES ON POOR ACIDIC SOILS,
Montana Univ., Missoula. School of Forestry.
C. Spitzner, and N. Stark.
Soil Science, Vol 134, No 6, p 395-400, 1982. 3 Tab, 21 Ref.

Descriptors: *Soil properties, *Productivity, *Drainage, Saline soils, Percolation, Leaching, Nutrients, *Montana, Subsurface water.

A study was conducted to determine whether variation in the subsurface percolation rate of underlying glacial till significantly affects the nutrient content of the andic surface soil or timber production on the andic soils. Twenty sites were sampled during the summer of 1980, covering a range of three percolation classes. All had ash depths of 18 to 50 cm, covering 160 m of elevational range and receiving an average of 950 to 1125 mm precipitation. All sites had western larches about 50 years of age. Analysis of the data and comparison of means for the various nutrient concentrations in the volcanic ash layers of the soil profiles did not show significant differences with changes in subsurface percolation rates, except for phosphate. Comparable leaching of the volcanic ash occurred on all sites, except for phosphate retention by the ash on the slowly drained soils. Ash on the slowly drained sites tended to be lower in most ions than ash on faster draining sites. Soil nutrients were significantly more abundant in the slowly drained sites. Soil nutrients were significantly more abundant in the slowly drained subsoils. Natural variability among site factors and physical differences in the subsoil may have contributed to this finding. Ion movement is likely to be influenced by the abundance of hydrogen ions in these soils. (Baker-FRC)

'BLUE' SOILS CAUSE COMPLEX DRAINAGE PROBLEMS,
California Univ., Davis. Dept. of Land, Air and Water Resources.
B. R. Hanson, and L. D. Whittig.
California Agriculture, Vol 34, No 10, p 13-14, October, 1980. 2 Tab.

Descriptors: *Drainage, *Soil chemistry, *Saturated soils, Soil properties, Iron compounds, Hydraulic conductivity, Blue soils, Compacted soils, Soil compaction, Soil saturation, Soil texture, Anaerobic conditions.

Drainage conditions were investigated in an area with brown top soil underlain by blue, blue-gray, and mottled saturated soils. Although the texture of the soils indicated that water movement was adequate for a drainage system, the hydraulic conductivity in the blue layer was extremely low. This low hydraulic conductivity is believed to be the result of reduced iron and high organic matter content of the soil. Under these conditions ferrous hydroxide is formed and precipitated out of the water, forming a gelatinous substance, which compacts the soil. Drainage to oxidize the iron was impossible in this situation because of poor drainage conditions and frequent wetting by rainfall and irrigation. It was suggested that a shallow drainage system be installed only in the top soil to provide a suitable root zone environment for agricultural purposes. (Cassar-FRC)

SOME EFFECTS OF LINEARIZING THE UNSATURATED SOIL MOISTURE TRANSFER DIFFUSIVITY MODEL,
California Univ., Irvine. School of Engineering.
T. V. Hromadka, and G. L. Guymon.
Water Resources Research, Vol 16, No 4, p 643-650, August, 1980. 15 Fig, 2 Tab, 11 Ref.

Descriptors: *Soil water, *Diffusivity coefficient, *Infiltration, Wetting, Finite element method, Crank-Nicolson Model, Galerkin model, Unsaturated flow, Model studies.

Unsaturated soil moisture transfer in a horizontal column was estimated using the Galerkin method combined with the Crank-Nicolson time advance approximation. The Galerkin technique was used for the quasi-linear spatial discretization problem, and the Crank-Nicolson technique was used with a diffusivity coefficient update method. For the constant diffusivity coefficient problems a modified capacitance matrix scheme significantly improved results over the standard finite element capacitance matrix. Five methods of estimating quasi-constant soil water diffusivity equivalents were evaluated. The resulting moisture content profiles from both the modified and unmodified capacitance matrix formulations were compared with the known Philip's solution for each of the five quasi-constant diffusivity computational schemes. Best results were obtained with the unmodified finite element capacitance matrices based values of diffusivity coefficients evaluated as the mean parabolic value of the state variable (water content). (Cassar-FRC)

2H. Lakes

SENSITIVITY OF OREGON'S CASCADE LAKES TO ACID PRECIPITATION,
Oregon State Univ., Corvallis. Dept. of Civil Engineering.
P. O. Nelson, and G. K. Delwiche.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111780, Price codes: A04 in paper copy, A01 in microfiche. Water Resources Research Institute Publication WRRI-85, Oregon State Univ., Corvallis, September 1983. 55 p, 7 Fig, 3 Tab, 35 Ref, 3 Append. OWRT A-061-ORE(1), 14-34-0001-2139.

Descriptors: *Acid rain, Precipitation, Lakes, Oligotrophic lakes, Lake contamination, Chemical properties, *Carbonates, *Oregon carbon, *Dissolved organic carbon, Dissolved aluminum, *Dilute-lake chemistry, Buffering capacity, *Oregon, Oregon cascades, Oregon lakes, *Oregon cascade lakes.

Susceptibility to acidification and present extent of anthropogenic acidification were studied for 63 Oregon Cascade lakes in 1982. Chemical parameters included pH, conductivity, alkalinity, calcium, magnesium, sodium, potassium, dissolved silica, chloride and sulfate. Major ion balances were calculated. Analyses for total organic carbon, fluoride and aluminum were performed in some cases. The lakes have extremely dilute ionic compositions. Average conductivity was 17.0 umhos/cm. Average laboratory-equilibrated pH was 6.96. Alkalinities averaged 137.6 ueq/l; 25 lakes had alkalinities of less than 50 ueq/l. Calcium was the major cation (36%) and bicarbonate was the major anion (82%) present. Aluminum and sulfate concentrations were extremely low. The carbonate system was found to be the dominant buffer system. Extremely low alumunim and total organic carbon concentrations indicate the minor contribution of aluminum hydrolysis species and weak organic acids to the overall acid neutralizing capacity of these waters. The calcium-to-bicarbonate ratio and the low dissolved aluminum and sulfate concentrations show that anthropogenic acidifications is undetectable to date. Oregon's Cascade lakes do not presently have an acid precipitation problem but are extremely susceptible to acidification. The lakes can serve as a chemical benchmark to compare with acidified lakes of similar volcanic geology.

EFFECT OF LOW PH ON THE CHEMICAL COMPOSITION OF AQUATIC INVERTEBRATES FROM TUNDRA PONDS AT THE SMOKING HILLS, N.W.T., CANADA,
Toronto Univ. (Ontario). Dept. of Botany.
M. Havas, and T. C. Hutchinson.
Canadian Journal of Zoology, Vol 61, No 1, p 241-249, 1983. 6 Fig, 3 Tab, 21 Ref.

Descriptors: *Hydrogen ion concentration, *Acidic water, *Crustaceans, *Aquatic insects, *Tundra, *Alkaline water, Ponds, Chemical properties, Sulfates, Mortality, Daphnia, Sodium, Chlorine, Potassium, Chemical reactions, Aluminum, Northwest Territory.

The effect of low pH due to natural sulfate fumigation on the elemental composition of crustaceans and insect larvae collected from strongly acidic and alkaline tundra ponds at the Smoking Hills, Northwest Territory were examined. Analysis of mortality rates suggested that crustaceans Daphnia middendorffiana, Diaptomus arcticus, Branchinecta paludosa, Lepidurus articus and Diptera Orthocladuis consobrinus were more sensitive to low pH than were insect larvae due to their inability to maintain high internal levels of sodium (Na), Chlorine (Cl), and potassium (K). K levels were also low in dead and moribund Daphnia, but not in the more tolerant Diptera larvae. D. middendorffiana recovered following a brief exposure to pH 4.0 in which Na and Cl concentrations returned to their original levels. Acid-exposed Daphnia became infected by pathogenic fungi. Water chemistry also altered the chemical composition of some of the aquatic invertebrates studied, probably due to the elevated aluminum levels in the acidified pond water. (Geiger-FRC)

EXPERIMENTAL STUDIES ON THE FACTORS LIMITING TROPOCYCLOPS PRASINUS (FISCHER) 1860 IN AN OLIGOTROPHIC LAKE,

British Columbia Univ., Vancouver. Inst. of Animal Resource Ecology.
A. Peacock, and W. J. P. Smyly.
Canadian Journal of Zoology, Vol 61, No 1, p 250-265, 1983. 13 Fig, 10 Tab, 50 Ref.

Descriptors: *Copepods, *Cyclops, *Population dynamics, *Population density, *Oligotrophic lakes, Temporal distribution, Crustaceans, Aquatic populations, Predation, Seasonal variation, Food chains, Mortality, *British Columbia, Placid Lake, Gwendoline Lake.

Factors affecting the relative abundances of Tropocyclops prasinus and Cyclops bicuspidatus thomasi in a small oligotrophic lake (Placid Lake) in coastal British Columbia were examined in laboratory feeding experiments. T. prasinus, which is abundant in the lake, was omnivorous in the later instars but showed no signs of cannibalism or predation on other microcrustaceans. Adult diets of T. prasinus and C.b. thomasi (rate in the lake) did not overlap; however, seasonal abundance peaks revealed a temporal segregation of the anupliar instars of both cyclopoid copepods. Chaoborus flavicans ate more C.b. thomasi than T. prasinus, but in laboratory beakers, in the absence of Chaoborus, C.b. thomasi always outnumbered T. pasinus after 50 or 100 days. Results of large scale exposure experiments showed that lake densities of C.b. thomasi could limit the abundance of T. prasinus in Placid Lake. T. prasinus naupliar mortality was high, even in the absence of C.b. thomasi. In the presence of C.b. thomasi, mortality of nauplius 4 to copepodid I instars was greatly increased. (Geiger-FRC)

THE MACROINVERTEBRATE FAUNAS OF RIFFLES AND POOLS,
University of Wales Inst. of Science and Technology, Cardiff. Dept. of Applied Biology.
P. Logan, and M. P. Brooker.
Water Research, Vol 17, No 3, p 263-270, March 1983. 2 Fig, 5 Tab, 38 Ref.

Descriptors: *Invertebrates, *Aquatic habitats, *Population density, Macroinvertebrates, Riffles, Pools, Aquatic populations, Aquatic insects, Insects, Stream biota, Classification, Species composition.

Macroinvertebrate population data from 17 studies of rivers (mostly upland) in North America and the United Kingdom were examined for differences in fauna inhabiting pools and riffles. Most of the numbers and taxa were similar in both habitats, but Simulium and Corixa were characteristic of riffles and pools, respectively. Riffles had significantly higher population densities than pools. Generally, Ephemeroptera accounted for a higher proportion of the total density in riffles than in pools. Diptera covered a higher proportion in pools than in riffles. Ephemeroptera represented the only taxa to show significant differences in density between the two habitats, riffles supporting higher densities than pools. The overall ratio for total density (riffles/pools) was 1.1. Only Baetidae and Simuliidae families showed significant differences in density, riffle density being greater than pool density. Results of this study indicated that sites will probably be classified correctly with respect to biological monitoring whether samples are collected in riffles or pools. However, these conclusions should not be applied to lowland rivers, for which insufficient data exist. (Cassar-FRC)

SELF-PURIFICATION OF WATER AS A FUNCTION OF PHYSIOLOGY OF MACROPHYTES,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
K. B. Yakubskiy, and A. I. Merezhko.
Hydrobiological Journal, Vol 18, No 2, p 63-68, 1982. 1 Fig, 2 Tab, 36 Ref.

Descriptors: *Macrophytes, *Water purification, Self-purification, Water quality, Water quality control, Lakes, Reservoirs, Aquatic plants, Pondweed, Reeds, Oxygen, Nutrients, Calcium, Minerals, Potassium, Chlorine, Biomass.

In a body of water, self-purification is closely related to the vital activity of macrophytes and their biological pecularities. Common reed, as a typical representative of subaerial littoral vegetation, exhibits high rates of photosynthesis and active absorption of nitrogen and silicon. It forms a large phytomass, the quantity of which is closely related to the presence of nutrients in the substrate, their absorption, and thus the self-purification of water and high water quality. The phytosynthesis in perfoliate pondweed (submerged vegetation) proceeds at a lower rate, but gas exchange occurs within the water, so that its aeration capacity is higher than that of reed. Pondweed also has high absorption capacity in that it absorbs double the quantity of mineral elements per unit of generated biomass compared to the reed, particularly such elements as potassium, calcium and chlorine. For intelligent use of these macrophytes as biofilters both under natural conditions and in artificial water purifiers, allowance must be made for their biology, particularly their aeration and absorptive capacity. A. Konopka, K. M. Brown, and C. R. Lovell.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113679, Price codes: A07 in paper copy, A01 in microfiche. Technical Report No 161, September 1983. 126 p, 11 Fig, 70 Tab, 76 Ref. OWRT B-127-IND(1), 14-34-0001-1225.

Descriptors: *Bacteria, *Phytoplankton, *Zooplankton, *Primary productivity, Lakes, Photosynthesis, *Food chains, Food webs, *Indiana, Crooked Lake, Little Crooked Lake.

The relationship between phytoplankton, bacteria, and zooplankton activities and distributions was studied in two Indiana lakes: Crooked and Little Crooked. Primary production in the metalimnion was an important source of fixed carbon in these lakes. In Crooked Lake, metalimnetic production accounted for 30-45% of the total production, during the summers of 1979-1981. Changes in the vertical distribution of biomass in the water column had a greater effect upon metalimnetic production than differences in water transparency or incident solar radiation. Excretion of organic carbon by phytoplankton populations is a potentially important source of carbon for heterotrophic bacteria. The photosynthetic rates of water samples were proportional to light intensity and increased from 1.42 to 3.14 mg C mg super -1 chlorophyll a hr super -1 within a range of light intensities from 65 to 150 mu E m super -2 sec super -1. Elevated oxygen concentrations in samples incubated at 150 mu E m super -2 sec super -1 decreased rates of both photosynthesis and excretion. The photosynthetic rate increased from 3.0 to 5.0 mg C mg super -1 chlorophyll a hr super -1 as the pH was raised from 7.5 to 8.8. Calculation of total primary production using a numerical model showed that whereas 225.8 g C m super -2 was photosynthetically fixed during the period between May 12 to August 24, 1982, only g C m super -2 was excreted by phytoplankton. Heterotrophic bacterial activity in the two lakes generally correlated very well with the distribution of phytoplankton. Bacterial activity was primarily associated with planktonic bacteria rather than cells attached to particles. Several zooplankton species found in the lake were capable of ingesting bacteria and unicellular cyanobacteria but could not feed on filamentous cyanobacteria, the most important phytoplankton in the lakes.

REPORT OF THE WORK GROUP ON WETLANDS (INCLUDING RICE) AND AQUATIC SYSTEMS,
K. R. Reddy, V. Montecino, A. J. Holding, U. Irmler, and P. S. C. Rao.
Plant and Soil, Vol 67, No 1-3, p 421-424, 1982. 1 Tab, 5 Ref.

Descriptors: *Wetlands, *Rice, *Nitrogen, Research priorities, *South America, Lakes, Rivers.

A summary report on a wetlands study reveals that the area (in sq km) occupied by various fresh water ecosystems in Latin America is: lakes, 62,000; river basins; 8.1 million; and rice fields, 54,000 (upland) and 21,000 (irrigated). Of the research priorities listed, nitrogen budgets and associated model studies are of primary importance. Using data from the southern U.S., N fluxes were estimated for rice ecosystems in Latin America: influx, 159-325 kg N per ha (largest amounts from fertilizer and soil N mineralization); output, 116-335 kg N per ha (largest amounts from harvest and denitrification). (Cassar-FRC)

THE SPECIES AND SIZE COMPOSITION OF TROPICAL FRESHWATER ZOOPLANKTON WITH SPECIAL REFERENCE TO THE ORIENTAL REGION (SOUTH EAST ASIA),
Waterloo Univ. (Ontario). Dept. of Biology.
C. H. Fernando.
Internationale Revue der Gesamten Hydrobiologie, Vol 65, No 3, p 411-426, 1980. 2 Fig, 6 Tab, 108 Ref.

Descriptors: *Zooplankton, *Lakes, *Species composition, Asia, India, Tropical regions, Temperate zone, Clacoderans, Copepods, Rotifers, Species diversity, Daphna.

The zooplankton population of Southeast Asia (encompassed by India and Nepal in the west, the Philippines in the east, and Indonesia in the south) showed a gradual change from the northern and southern temperate regions to the tropical region. Data was gathered from over 2500 samples collected from 1200 localities during 1968-1977. The number of Cladocera and Copepoda species was much less in the tropical region than in the temperate regions. Daphnia were scarce and small in the tropics and increased in size, number, and diversity toward the temperate zones. This was also true for Holopedidae, Leptodoridae, and Polyphemidae. The littoral zooplankton, Eruycerus and Saycia, were absent or very rare in the tropics compared with the temperate zones. Only two cyclopoids, the herbivorous Thermocyclops crassus and the carnivorous Mesocyclopsleukarti, were common in the tropical region. The most common rotifers were Brachionus and Keratella tropica. Endemic and unexpected Cladocera reported were Alona macronyx Daday, Chydorus faviformis Birge, Alonella nana Baird, and Indialona ganapati Petrovski. (Cassar-FRC)

SEASONAL CYCLES OF ZOOPLANKTON AND RELATED PHYTOPLANKTON DEVELOPMENT IN THREE SHALLOW, MESOTROPHIC LAKES IN NORTHERN CANADA,
Alberta Environmental Center, Vegreville.
J. W. Moore.
Internationale Revue Der Gesamten hydrobiologie, Vol 65, No 3, p 357-378, 1980. 7 Fig, 4 Tab, 49 Ref.

Descriptors: *Zooplankton, *Population density, *Food habits, Lakes, Phytoplankton, Seasonal variation, Mesotrophic lakes, Canada, Temperature effects, Subarctic zone, Grace Lake, Long Lake, Madeline Lake.

The seasonal cycles of zooplankton and phytoplankton development were studied during April 1978 to April 1979 in three shallow, mesotrophic lakes (Grace, Long, and Madeline) in northern Canada. The lakes were similar in nannoplankton density (50-450 mg per cu m in summer), net phytoplankton density (200-1600 mg per cu m in summer), temperature, depth (11-17 m), oxygen

concentration, and phosphorus levels. Most common nannoplankton species were Nannochloris bacillaris, Rhodomonas minuta var. nannoplanktonia, Ochromonas, and other phytoflagellates. Main phytoplankton taxa were Dinobryon and filamentous cyanophytes. The seasonal changes in zooplankton species (Keratella cochlearis, Kellicottia longispina, Polyarthra vulgaris, Polyarthra remata, Cyclops, Diaptomus ashlandi, Daphnia longiremis, and Codonella cratera) were similar in the three lakes. Changes in densities of these species were not statistically correlated with fluctuations in nannoplankton availability, implying that food did not limit development. Although predatory copepods were abundant, they had no measurable impact on the main species. It was concluded that temperature was the most important factor regulating the seasonal cycles and the population sizes of most zooplankton. (Cassar-FRC)

TROPHIC UPSURGE IN NEW RESERVOIRS: A MODEL FOR TOTAL PHOSPHORUS CONCENTRATIONS,
Department of the Environment, Sainte-Foy (Quebec).
Y. Grimard, and H. G. Jones.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 39, No 11, p 1473-1483, 1982. 5 Fig, 1 Tab, 38 Ref.

Descriptors: *Reservoirs, *Phosphorus, Nutrients, Model studies, Trophic level, Canada, Canadian Shield.

A model is presented for total phosphorus concentrations during both the trophic upsurge and depression phases in new reservoirs. The model was developed by a convolution of the rate of phosphorus leaching from flooded lands and the rate of reservoir filling. Model parameters for phosphorus sedimentation and leaching coefficients were estimated from data available on the Smallwood Reservoir (impoundment 1971) in Labrador. The model was then applied to predict phosphorus concentrations during the trophic upsurge phase in the La Grande-2 Reservoir (impoundment 1978) in the James Bay region of Quebec. Because the sparse data available on other new or old reservoirs during the trophic upsurge phase does not permit an analysis of the confidence limits in model output, discussion of the calculated values of model parameters and their relationship to the real phenomena are included. An evaluation of the rates of phosphorus leaching from various lands has shown indirectly that the proposed model approximates the dynamics of new reservoir phosphorus concentrations. It is concluded that the model as defined bears some promise as the base for an empirical model, although compatible data on reservoir systems are rare. Confidence in the model is enhanced, as the values of certain model parameters are of the same order of magnitude as those calculated by independent means. The model has a good potential as an empirical predictive tool in the management of large new reservoirs on the Canadian Shield. (Baker-FRC)

Transactions of the ASAE, Vol 26, No 1, p 87-91, 99, 1983. 5 Fig, 2 Tab, 10 Ref.

Descriptors: *Soil properties, *Soil-water-plant relationships, Model studies, Richard's equation, Mathematical studies, Mathematical equations, Permeability.

Mathematical models for simulating water transport in soils containing roots have been extremely useful for increasing the understanding of soil-water-plant relationships. Such models are currently being used in the design of various water and waste management systems where soils are relatively wet much of the time. Consideration is given to the case of one-dimensional, vertical movement of water in a soil containing the roots of transpiring plants. Mathematical complexity is thus kept to a minimum while the basic physical principles are described. The results can be generalized to multi-dimensional situations. A physically based root extraction relation for use in Richard's equation is proposed. The extraction function assumes that the water uptake rate per unit volume of soil is proportional to the product of contact length per unit soil volume, root permeability per unit length and water potential difference between soil annd root xylem pot volume of soil is proportional to the product of contact length per unittential, which is assumed to be constant over the root zone. Herkelrath's factor, which accounts for reduced root-soil-water contact as water is removed, was included. Thus the model should be applicable in any system involving lighter texture soils kept relatively wet. Model predictions compared favorably with the results of a previously performed experiment. A. W. Knight.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111673, Price codes: A03 in paper copy, A01 in microfiche. California Water Resources Center Completion Report, Univ. of California, Davis, October 1983. 33 p, 14 Fig, 3 Tab, 25 Ref. OWRT A-085-CAL(1).

Descriptors: *Centrifugation, Separation techniques, *Sediment sorting, *Estuaries, *Algae, Sediment-water interfaces, Bottom sediments, Sediment concentration, Marine concentration, Suspended concentration, Toxicity.

Development of a simple and inexpensive density gradient centrifugation method, utilizing silica sols, for separating and isolating various fractions of suspended matter and bottom sediments was begun. There is presently no effective means for fractionating suspended material in natural waters into its natural components. The technique will be especially useful for researchers in estuarine productivity and toxicology. The influence of preservatives and density shift reagents on the separating and resolving powers of the centrifugation method has been analyzed. In addition the interaction between the method and the density shift reagents and preservatives on analysis of chlorophyll a, proteins, and carbohydrates was examined. Preliminary results indicate that the development of suitable methodology will require considerable additional effort. The technique has demonstrated that it is an important means of separating certain algal associations. (Snyder-California)

SEDIMENT TRANSPORT BY WAVES AND CURRENTS,
British Columbia Univ., Vancouver. Dept. of Civil Engineering.
M. C. Quick.
Canadian Journal of Civil Engineering, Vol 10, No 1, p 142-149, 1983. 6 Fig, 13 Ref.

Descriptors: *Sediment transport, *Wave action, *Water currents, Laboratory studies,.

The combined action of waves and currents on sediment transport was studied in a laboratory flume with a sand bottom, wave paddle, and current generator. Sediment transport direction was mainly determined by the direction of the wave movement, even in the presence of adverse currents, until waves started to break. Mass transport wave velocity increased in the presence of adverse currents, so that sediment still moved slowly in the direction of wave advance. Waves moving into a region of stronger adverse currents became steeper. When they began to break, the mass transport velocity at the bed fell to zero, and sediment transport then followed the direction of the adverse current. A transport power relationship was developed to predict the sediment transport rate. This agreed with the measured sediment transport rates. (Cassar-FRC)

SEMI-EMPIRICAL CORRELATIONS FOR FINE AND COARSE COHESIONLESS SEDIMENT TRANSPORT,
Lamar Univ., Beaumont, TX.
P. A. Mantz.
Proceedings of the Institution of Civil Engineers. Part 2: Research and Theory, Vol 75, No 1, p 1-33, 1983. 6 Fig, 13 Tab, 28 Ref.

Descriptors: *Bed load, *Sediment load, *Sediment transport, *Theoretical analysis, *Resistance, *Mathematical, Sediment distribution, Streamflow, Suspended load, Shear stress, Flow velocity.

The equilibrium sediment transport, bedform development and hydraulic resistance for three grades of almost equal-sized silica solids were studied under three flow depths and six conditions of average flow velocity. Sediment transport was analyzed according to the streampower theory developed by Bagnold, assuming that the rate of applied flow energy was dissipated partly by the friction of moving bed load solids, partly by the turbulence associated with bedforms, partly by the gravitational settling of suspended load solids, and partly by the friction of the unimpeded flow. Correlations were generated for the work rates associated with the moving bed load or suspended load and the streampower excess, which excludes that required for incipient transport or incipient suspension. Field data were compared with laboratory data, and bed load data were abstracted from a recent collation by Bagnold. Suspended load data were abstracted from river data of the United States Geological Survey. The present research expands the three classes of rivers according to Bagnold to take into account coarse and fine sediments, shallow and deep flows and streams of non-rectangular cross-section or a meandering stream. DETERMINATION OF BEDLOAD TRANSPORT USING NATURALLY MAGNETIC TRACERS: FIRST EXPERIENCES AT SQUAW CREEK, GALLATIN COUNTY, MONTANA,
Freie Univ. Berlin (Germany, F.R.). Inst. fuer Physische Geographie.
P. J. Ergenzinger, and S. G. Custer.
Water Resources Research, Vol 19, No 1, p 187-193, February, 1983. 4 Fig, 3 Tab, 12 Ref.

Descriptors: *Sediment transport, *Bed load, *Magnetic studies, Tracers, Squaw Creek, *Montana, Measuring instruments.

A detector which records the movement of naturally magnetic pebbles and cobbles in a stream bed was evaluated in Squaw Creek, Montana, during a 10-year flood in May 1981. Particles over 32 mm in diameter were detectable by the instrument. Correction factors accounting for the 85% of pebbles which were not magnetic, the smaller particles not detected (2/3 of total particles), and width of the creek allowed estimation of the total bedload transport. The bedload accounted for 66% of the total solid material (3400 metric tons) leaving the drainage basin during the flood. The rate of transport of suspended load varied from 200-400 kg per hour at the onset to 146,000 kg per hour at the peak stage. The peak in suspended load corresponded with the peak in water discharge. The rate and timing of bedload transport did not correspond as well to water discharge. (Cassar-FRC)

Water Resources Bulletin, Vol 19, No 1, p 29-35, February, 1983. 4 Fig, 2 Tab, 24 Ref.

Descriptors: *Model studies, *Erosion, Mathematical equations, Universal soil loss equation, Rills, Interrills, Sediment transport, Sedimentation.

A computer model of soil loss on an upland watershed has been developed from the continuity considerations for sediment transport and from equations describing rill and interrill erosion. The model is based on dividing the upland area into a grid containing rill and interrill zones, on the Universal Soil Loss Equation, and on equations describing detachment and transport capacity of rill flow. The USLE estimates the sediment load from the contributing areas. The location and amount of total erosion and deposition are determined by comparing the transport and detachment capacity of rill flow for specific storms. The model considers the mechanics of the erosion process and can serve as a basis for reservoir and channel design and land use planning. Interception, though neglected in the numerical example presented, is included in the model. (Baker-FRC)

TRANSPORT OF SAND-SIZED SEDIMENT ALONG CROP-ROW FURROWS,
Agricultural Research Service, Oxford, MS. Sedimentation Lab.
L. D. Meyer, B. A. Zuhdi, N. L. Coleman, and S. N. Prasad.
Transactions of the ASAE, Vol 26, No 1, p 106-111, 1983. 1 Fig, 2 Tab, 15 Ref.

Descriptors: *Sediment transport, *Erosion control, Sand, Rainfall-runoff relationships, Sedimentation, Erosion.

Sediment transport capacity was evaluated along simulated crop row furrows as influenced by furrow gradient, flow rate, sediment size and the presence or absence of rainfall. Only sand-sized sediment of single-particle density was studied. Four sand size groups averaged 77, 151, 302, and 603 micrometers for furrow gradients of 0.2, 1.0, 2.5, and 5.0% at flow rates of about 26, 39, 52 and 65 kg/min with and without intense simulated rainfall. Sediment tranport capacity increased rapidly as furrow gradient increased. The capacity was very small at 0.2%, but it became quite large at gradients above 1%. Transport capacity increased as flow rate increased, but the effect was less than that of furrow gradient. Transport capacity generally increased as particle size decreased below 300 micrometers. Rain falling on the furrow flow did not appreciably affect sediment transport for the conditions tested. The mode of sediment transport changed from isolated barchan dunes to transverse bars to streaky sheets of sediment as the furrow gradient increased. Development of the streaky sheet mode of transport was delayed by rainfall, and the change from bars to streaks occurred at about 1% gradient. (Baker-FRC)

A SMALL-SCALE FLOOD PLAIN,
Rhodes Univ., Grahamstown (South Africa). Hydrological Research Unit.
D. A. Hughes, and J. Lewin.
Sedimentology, Vol 29, No 6, p 891-895, 1982. 3 Fig, 1 Tab, 9 Ref.

Descriptors: *Flood plains, *Deposition, *Sediment sorting, *Sedimentation, Deltas, Suspended sediments, Alluvial deposits, Sediment distribution, Sediment transport, Overflow, Levees, Sedimentology, *Wales, River Rheidol.

A miniature flood plain was formed at a gravel extraction and washing plant on the River Rheidol, Wales. Washing water with high concentrations of fine sediment was channeled into a pit producing a small-scale delta, channel, and flood plain system about 9 m wide. The system developed levees, crevasse splays, and flood basins. Overbank sedimentation was dominant. Median sediment size decreased exponentially with distance from the channel center. At a meander bend coarser sediments were deposited on the outside of the bed. Sorting also improved with distance from the channel. The finest sediments were deposited in the stiller and deeper water. Deposits in the flood plain were laminated or very thinly bedded, without cross stratification. This was a result of variations in sediment supply from different gravels and relocation of crevasses and overflows. (Cassar-FRC)

HIGH SEDIMENT YIELDS FROM MAJOR RIVERS OF THE WESTERN SOUTHERN ALPS, NEW ZEALAND (DISCUSSION AND REPLY),
J. Adams, and G. A. Griffiths.
Nature (London), Vol 287, No 5777, p 88-89, September 4, 1980. 10 Ref.

Descriptors: *Erosion rates, *Suspended sediments, *Mathematical studies, Sedimentation, Suspended load, Rivers, *New Zealand, Flow characteristics, Dissolved solids, Bed load, Sediment load.

This response to a previous article by G. A. Griffiths (Nature, Vol. 282, p 61-63, 1979) suggests that Griffiths took too little heed of published data on sediment yields from major rivers of the western Southern Alps in New Zealand and underreported the suspended load data available. Griffiths reported data on suspended sediment yields from fewer rivers than had previously been reported and applied a traditional approach to calculation of suspended loads which had been questioned by the commentator. The commentator and the author used the same data on sediment loads, but reached significantly different estimates of loads in some cases. The author responds that the commentator had made assumptions in earlier studies which were not substantiated and that data which he presented was not always adequately identified. Griffiths charges that Adams did not make good use of his data, that some evaluations of the data were arbitrary, and that the results of the earlier study were not repeatable. (Carroll-FRC)

MINERAL PRECIPITATION IN NORTH SLOPE RIVER ICINGS,
National Aeronautics and Space Administration, Greenbelt, MD. Goddard Space Flight Center.
D. K. Hall.
Arctic, Vol 33, No 2, p 343-348, June, 1980. 3 Fig, 12 Ref.

Descriptors: *Calcium carbonate, *Groundwater, *Chemistry of precipitation, *Rivers, *Ice formation, Calcium compounds, Chemical properties, Ice, Arctic zone.

Patches of powdered calcium that were found on icings (aufeis) in the Canning and Shaviovik Rivers in northern Alaska suggest that much of the water feeding the aufeis fields comes from depth and has flowed through calcareous bedrock. Aufeis forms in winter at or below the point of groundwater discharge or when river water is forced up through cracks in river ice. Calcium carbonate is excluded during groundwater freezing and accumulates as slush on top of the ice as the aufeis ablates during the melt season. During a July 1978 field study, four patches of calcium carbonate covering about 0.1% of the total area of the Canning River aufeis were observed. If similar percentages of calcium carbonate precipitate were present on other major aufeis fields on the eastern North Slope, about 18000 cu m of calcium carbonate may be present during a given year in these aufeis fields. The majority of this precipitate is deposited into the Arctic Ocean via river flow. (Geiger-FRC)

NITRATE DEPLETION IN A SECOND-ORDER MOUNTAIN STREAM,
Southeastern Forest Experiment Station, Asheville, NC. Coweeta Hydrologic Lab.
W. T. Swank, and W. H. Caskey.
Journal of Environmental Quality, Vol 11, No 4, p 581-584, October-December, 1982. 2 Fig, 5 Tab, 20 Ref.

Descriptors: *Denitrification, *Nutrients, *Sediments, Coweeta Hydrological Laboratory, North Carolina, Forest watersheds, Streams, Nitrogen, Logging, Clear-cutting.

Denitrification was studied in Coweeta Hydrological Laboratory, a 2270 ha hardwood forest site in the Appalachian Mountains of North Carolina, for 4 years starting June 1976. During this period logging roads were cut, resulting fills and cuts were stabilized with seeding and liming, and logging was conducted (first half of 1977). Within-stream depletions of nitrate-N from upper to lower reaches of the second-order stream were 127% of total nitrate-N discharged at the outlet the first year, and 99%, 42%, and 5% in succeeding years. Nitrate-N depletion was 3.3 kg the first year, and 27.9, 32.4, and 3.9 kg in succeeding years. Denitrification in the sediment, measured by enzyme assay, produced a loss of 1.7 kg N during the final year of the study. This suggests that sediment denitrification is a major pathway for nitrate-N loss. Neglect of this factor in studies of N dynamics can result in underestimation of N losses in streams. (Cassar-FRC)

EFFECTS OF LIGHT, TEMPERATURE AND SALINITY ON THE PHOTOSYNTHETIC PATTERN IN AN ESTUARINE PHYTOPLANKTER FROM CHESAPEAKE BAY,
Agricultural Research Service, Beltsville, MD.
D. E. Terlizzi, and E. P. Karlander.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111871, Price codes: A03 in paper copy, A01 in microfiche. Water Resources Research Center Technical Report No 72, Univ. of Maryland, College Park, August 1983. 22 p, 7 Fig, 27 Ref. OWRT A-059-MD(1), 14-34-0001-2122.

Descriptors: Light, Temperature, *Salinity, *Photosynthesis, *Phytoplankton, Interactions, Stress, Protein, Lipid, Polysaccharide, Free metabolites, *Chesapeake Bay, *Maryland.

The effects of the variables; light intensity, temperature, and salinity on the growth rate and the pattern of NaH super 14 CO sub 3 photoassimilation in a coccoid nanoplankter from the Chesapeake Bay (UTEX 1998) were examined. While growth rates were depressed in some instances as a result of a change in medium composition, results generally support earlier conclusions that this organism has a relatively high temperature optimum and favors moderate salinities. Although the response to stress observed by other workers of an enhanced relative incorporation of super 14C into the protein fraction is not always observed, it does occur at 15C and 35 o/oo at all light intensities examined and at 30C under the same light intensities and salinity. In comparing the super 14C fractionation data with growth rate, several trends were observed: (1) Protein super 14C generally increased with increasing growth rate at 15C, (2) Polysaccharide super 14C tended to increase with growth rate at 15 and 30C, but optima at intermediate growth rates were observed at 20C, (3) super 14C incorporation into the lipid fraction decreased with increasing growth rate, (4) Free metabolite super 14C decreased with increasing growth rate except at 20C. The data demonstrate that trends in the photosynthetic pattern as a function of growth rate are regulated by the major physico-chemical parameters of the estuarine environment.

A TWO-DIMENSIONAL NUMERICAL MODEL OF ESTUARINE CIRCULATION USING CUBIC SPLINES,
Ecole Polytechnique, Montreal (Quebec). Dept. of Civil Engineering.
P. Wang, and R. Kahawita.
Canadian Journal of Civil Engineering, Vol 10, No 1, p 116-124, 1983. 10 Fig, 11 Ref.

Descriptors: *Saline water intrusion, *Tidal effects, *Water circulation, Mixing, Estuaries, Spline function, Model studies, Great Whale River, Stratification, *James Bay region.

Velocity and salinity distributions along an estuary have been described by a two-dimensional, laterally integrated numerical model. Governing equations, which express the dynamics of a partially mixed estuary, consist of continuity, momentum balance, and salt and/or heat balance equations, together with an equation of state. They are solved by a finite difference method combined with spline functions. The model was applied to a study of the Great Whale River, James Bay, Canada. The effects of stratification on the salinity distribution were determined. Computed vertical velocity profiles corresponded with the observed dominant upstream current in the lower layers even at ebb tide. At high tide the flow at the river mouth reverses completely. Field data for calibrating this model is not yet available. (Cassar-FRC)

A seasonal study of the transport processes controlling dissolved gas distributions in the sediment of a small marine basin, Cape Lookout Bight, North Carolina, was conducted to identify seasonally varying mechanisms of dissolved gas sediment-water exchange and to quantify rates of stripping dissolved gases from sediments during ebullition. Results showed that transport of dissolved gases in the anoxic sediments is controlled by diffusion and bubble ebullition and follows a seasonal cycle. Seasonal profiles of methane, nitrogen, argon and radon 222 gases and direct gas flux measurements showed that ebullition dominates the flux of all dissolved gases across the sediment-water interface during the summer months and is important on an annual basis. Transport in the upper 6-8 cm of sediment appears to be controlled by molecular diffusion of gases, while at greater depths it is controlled by diffusion in winter and ebullition in summer. Rates of stripping of dissolved gases within the methane production zone averaged 3-5%/day. Sediments of the bight are never at saturation with respect to the major gases present in seawater due to summer ebullition. Research at other sites suggests that ebullition may be an important transport process in many coastal sediments, and may serve as a mechanism for the transport of volatile reduced compounds between the atmosphere and anoxic sediments. A NUMERICAL MODEL OF CIRCULATION IN A CONTINENTAL SHELF-SILLED FJORD COUPLED SYSTEM,
Alaska Univ., Fairbanks. Inst. of Marine Science.
H. J. Niebauer.
Estuarine and Coastal Marine Science, Vol 10, No 5, p 507-521, May, 1980. 12 Fig, 26 Ref.

Descriptors: *Model studies, *Numerical analysis, *Fjords, *Subarctic zone, *Water circulation, Mathematical models, Estuaries, Continental shelf, Coriolis force, Water currents, Wind-driven currents, Advection, Alaska.

A cross-sectional numerical model of continental shelf-silled fjord coupled systems was constructed to simulate bottom water renewal processes in silled estuaries. The finite difference, time dependent model is non-linear and includes friction, stratification and topography while assuming no longshore propagation or advection. The model was applied to a high altitude subarctic fjord opening on to the Gulf of Alaska shelf. Modeling experiments on Resurrection Bay suggest that the Coriolis force should be taken into account in studying the bottom water renewal of narrow fjord basins. Coastal upwelling and downwelling on the adjacent shelf greatly affect fjord wide circulation and renewal. These findings suggest that deep-water renewal is almost continuous year round although the driving forces and associated results are strongly seasonal. The model results showed good agreement with hydrographic, meteorological and current data from the Resurrection Bay-continental shelf system.

GROUNDWATER-SOLUTE INFLUX,
Atomic Energy of Canada Ltd., Chalk River (Ontario).
D. R. Lee.
Limnology and Oceanography, Vol 25, No 1, p 183-185, January, 1980. 1 Fig, 19 Ref.

Descriptors: *Solute transport, *Groundwater, Marshes, Salt marshes, Great Sippewissett Marsh, Nutrients, Fluctuations.

Questions are raised concerning a previously published paper (Valiela, I., et al., Nutrient and particulate fluxes in a salt marsh ecosystem: tidal exchanges and inputs by precipitation and groundwater, Limnology and Oceanography, Vol. 23, p 798-812, 1978). According to the present discussion, it seems justifiable to conclude that groundwater may be an important source of nutrients to salt water, but the hydrogeologic features of the specific study area must be given due attention. For example, samples from springs may not be adequate for estimating the quality of groundwater entering a body of surface water. Dramatic variations in discharge from a regional groundwater flow system seem questionable. Estimated groundwater input to Great Sippewissett Marsh may differ from an estimate based on the Darcy equation. In the current study an independent estimate of probable groundwater flow to the marsh was made based on available hydrogeologic information and gave a much lower value, 1,500 cu m per tidal cycle, compared to the estimate of Valiela et al., 6,700 cu m per tidal cycle. Additional estimates of nitrogen loading of groundwaters were also made, and gave far lower nitrogen and salinity values than those in the original paper. (Baker-FRC)

FINAL REPORT ON THE TESTING OF THE ABSORPTION FREEZING VAPOR COMPRESSION PILOT PLANT AT THE WRIGHTSVILLE BEACH TEST FACILITY,
North Carolina State Univ. at Raleigh. Water Process Development Lab.
L. Fleming.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110741, Price codes: A06 in paper copy, A01 in microfiche. Final Report, September 30, 1982. 110 p, 15 Fig, 3 Tab, 5 Append. OWRT C-90227-D(NO 9530)(1), 14-34-0001-9530.

Descriptors: *Desalination apparatus, *Seawater, *Heat transfer, *Absorption freezing vapor compression, Energy consumption, Pilot plants, *Desalination plants, *North Carolina, Wrightsville Beach.

The absorption freezing vapor compression (AFVC) pilot plant is a vacuum freezing process which utilizes a concentrated sodium chloride solution to absorb the large volumes of low pressure water vapor produced in the freezer. This vapor is boiled off in a generator and used to melt the ice formed in the freezer. Seawater does not come in contact with any heat transfer surface nor with the refrigerant and therefore no contaminants are introduced into the aqueous system. Other advantages of the process include: low process temperatures, which reduces corrosion; low theoretical

energy requirements; and no need for pre-filtering of the feed water. The design objective of the plant was to demonstrate a specific energy consumption of 50 kWhr per 1000 gallons of product water at a production rate of 25,000 gpd. The pilot plant was started up in the fall of 1979. Steady state operation of the pilot plant was not achieved until November, 1980, when an auxiliary heat rejection compressor was installed. This compressor provided the capability to reject all the waste heat from the process and thus made steady state operation possible. The normal duration of runs was 100 hours. The plant was not capable of unattended operation. The longest period of uninterrupted steady state operation was approximately 48 hours. The maximum steady state open loop production rate achieved was 21,300 gpd on January 7, 1982. The specific energy consumption was 104 kWhr per 1000 gallons of product water for this run. The high rate of energy consumption was due largely to the poor performance of the absorber and generator heat exchangers and the higher than expected heat rejection load. (Moore-SRC)

MECHANISM AND MOLECULAR INTERACTIONS IN THE TRANSPORT OF WATER THROUGH MEMBRANES,
Agricultural Research Service, Albany, CA. Western Regional Research Center
J. R. Scherer, D. P. Malladi, G. F. Bailey, and S. Kint.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110832, Price codes: A05 in paper copy, A01 in microfiche. Completion Report, (1983). 81 p, 42 Fig, 2 Tab, 30 Ref. OWRT C-90297-S(No 9445)(1), 14-34-0001-0445.

Descriptors: *Cellulose acetate membranes, *Pore water, Absorption, Reverse osmosis, Polymers, Hydration, Polyimide membranes, *Desalination, Desalination processes, *Membrane processes.

Changes in waveguide properties of several cellulose acetate membranes and one polyimide membrane were measured as a function of their exposure to varying levels of relative humidity. The volume fraction of water in the films and the occupied pore volumes were determined from refractive index and thickness changes. The dependence of the refractive index on water absorption is related to a competition between two processes: 'pore filling' with no film expansion and 'free expansion' where the film expands to accommodate the added water volume. The hydration properties of these membranes are affected by degree of acetylation, casting temperatures and annealing treatments. Annealing CA398 membranes at 180 degrees C decreases film water concentration by reducing 'free expansion'. Annealed CA398 membranes that were tested in a reverse osmosis cell had high salt rejection compared to unannealed films. The hydration characteristics of a polyimide membrane are compared to cellulose acetate membranes. Raman measurements of unannealed CA and CTA membranes and annealed CA membranes using the waveguide technique showed that OH groups in unannealed polymers are all hydrogen bonded and are highly accessible to absorbed water. The intergrated OH stretching intensity in the region of 3050 to 3800 cm super -1 was found to be linearly dependent on water concentration. Water absorbed in the 'pore filling' stage is weakly hydrogen bonded to C=0 groups in the polymer and water absorbed in the 'free expansion' stage is hydrogen bonded like bulk water at equivalent 90 degrees C. Analysis of the C=0 stretching region indicated that each of the OH groups of a water molecule are H-bonded to a different C=0 group of the polymer in the 'pore filling' stage of absorption.

SECOND TUBINGEN SYMPOSIUM ON SYNTHETIC MEMBRANES IN SCIENCE AND INDUSTRY,
E. Bayer, and H. Strathmann.
In: Desalination, Vol 34, Nos 1/2, p 1-158, July-August, 1980 (Comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979). 75 Fig, 24 Tab, 121 Ref.

Descriptors: *Membrane processes, *Membranes, *Desalination, *Desalination apparatus, Desalination plants, Solute transport, *Synthetic membranes.

The main goal of the Symposium was to initiate a dialogue between membranes experts and possible users of synthetic membranes who were not interested in specific problems of membrane preparation techniques or transport phenomena but would like to find out how membranes can be utilized to solve problems in their specific area of interest. The symposium, which was organized by the Department of Organic Chemistry of the University of Tubingen, hosted more than 250 participants from 15 countries. The basis of synthetic membranes and their applications were described in 6 review lectures. In another 40 papers, the various aspects of synthetic membranes were discussed with the main emphasis concentrated on their practical use. With the rapid growth of industrial applications of membranes and membrane processes, a transition took place in the scientific community interested in synthetic membranes. In the early days of membrane research, mainly physical chemists were interested in this field. Today, scientists and engineers from various scientific disciplines are involved in the field of synthetic membranes. Polymer and organic chemists are mainly concerned with preparation of membranes with desired transport properties, physical chemists study these transport properties and develop new methods for their practical utilization, chemical engineers convert laboratory scale operations into efficient industrial processes.

SELECTION OF MICROPOROUS MEMBRANES FOR OPTIMUM SEPARATIONS,
Nuclepore Corp., Pleasanton, CA.
H. W. Ballew, and M. C. Porter.
In: Desalination, Vol 34, Nos 1/2, p 3-10, July - August, 1980 (Comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979). 5 Ref.

Descriptors: Separation techniques, Water purification, *Membranes, *Membrane processes, Desalination, *Microfiltration, *Microporous membranes.

There are basically only two types of microporous membranes commercially available; the screen type and the depth type. Each has numerous advantages and disadvantages. The user should carefully consider several characteristics in selecting which of the two types will perform the optimum separation. This paper compares the physical structure, chemical resistance, retention and other performance characteristics of the two types of membranes and summarizes how these differing characteristics may be utilized to maximum advantage in a variety of typical laboratory and industrial microfiltration applications.

LABORATORY EXPERIMENTS WITH HYPERFILTRATION MEMBRANES,
Heidelberg Univ. (Germany, F.R.). Inst. fuer Angewandte Physikalische Chemie.
W. Schneider, and O. Bauer.
In: Desalination, Vol 34, Nos 1/2, p 11-24, July - August, 1980 (Comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979) 4 Fig, 2 Tab, 6 Ref.

Descriptors: Separation techniques, Water purification, *Membranes, *Membrane processes, Model studies, Desalination, *Hyperfiltration membranes, Reverse osmosis.

The operation properties of hyperfiltration membranes are representable by various model concepts. The different mathematical relationships that are based on the respective models correspond to the known phenomenological ones and are suitable for describing the throughput through these membranes as well as their separation behaviour within a wide range of operation. Since those relationships are of the same analytical type, it is difficult to account for the mode of action of the membrane from these equations. Laboratory tests with RO membranes are reported with the aim of discussing experimental results which are not covered by the mathematical relationships or which deviate from them respectively. An analysis of these results seems to be helpful for extending the knowledge of the hyperfiltration process.

TREATMENT BY REVERSE OSMOSIS OF CERTAIN SOLUTIONS CONTAINING TWO SOLUTES, ONE ORGANIC AND ONE INORGANIC,
New South Wales Univ., Kensington (Australia). School of Chemical Engineering.
M. J. Clinton, and R. T. Fowler.
In: Desalination, Vol 34, Nos 1/2, p 25-34, July-August, 1980 (Comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979) 3 Fig, 1 Tab, 22 Ref.

Descriptors: Water treatment, Aqueous solutions, Solvation, Membranes, *Membrane processes, *Reverse osmosis, *Solutes, Sodium nitrate, Sodium sulphate, Urea, Glucose, *Solute transport, Desalination, *Electrolyte transport.

Experiments were performed to see whether equations developed to describe the reverse osmosis treatment of single-solute solutions would be applicable when the solutions to be treated contained both an ionic and a non-ionic solute. Four solutes were chosen: sodium nitrate, sodium sulphate, urea and glucose. Corrections to the traditional equations for electrolyte transport through the membrane were found to be necessary. For some of the two-solute solutions, a certain amount of solute-solute coupling was detected but its influence was small.

LOW TEMPERATURES AND DISSOLVED GASES: TWO PROBLEMS IN SUBMARINE SEA WATER DESALINATION,
Technische Univ., Munich (Germany, F.R.). Dept. of Chemical Engineering.
M. Hampe.
In: Desalination, Vol 34, Nos 1/2, p 35-56, July-August 1980 (comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979) 17 Fig, 4 Tab, 6 Ref.

Descriptors: *Membranes, *Membrane processes, Reverse osmosis, Ions, *Desalination, Seawater, Desalination processes, *Submarine desalination, Ionic rejections, Volume fluxes, Gas permeability.

The behavior of four types of reverse osmosis membranes for sea water desalination at temperatures between 0 degrees C and 20 degrees C was investigated. Besides the rejections of the ionic chief constituents of the sea water and the volume fluxes through the membrane, the permeabilities of gases dissolved in sea water, namely nitrogen, oxygen, argon and (total) carbon dioxide were determined. The volume fluxes show a not expected independance on pressure at temperatures near 0 degrees C. A possible explanation is given.
W84-00056

MEMBRANE/WATER DISTRIBUTION AND DIFFUSION OF NICKEL ION IN CELLULOSE ACETATE MEMBRANES,
G. Mossa, R. Passino, and M. Pegoraro.
In: Desalination, Vol 34, Nos 1/2, p 57-68, July-August 1980 (comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979). 5 Fig, 1 Tab, 12 Ref.

Descriptors: Separation techniques, Aqueous solutions, Membranes, Membrane processes, *Reverse

osmosis, *Cellulose acetate membranes, *Nickel ion, *Ion transport, Ions, Desalination.

In the framework of a study on the removal of metals from aqueous solutions by reverse osmosis, Ni super ++ diffusion and distribution between weakly charged cellulose acetate (CA) dense membranes and aqueous NiSO sub 4 were determined. NiSO sub 4 solutions with concentrations from 0.1 to 0.001 were used. The values of diffusion coefficients were found to be 10 to the minus 13 squ cm/s and practically independent of salt concentration. Distribution coefficient data varied as a function of the external solution concentration, according to Anderson's treatment of electrolyte sorption. The experimental data were in satisfactory agreement with Glueckauf's physical model of distribution, at sufficient high concentrations.

SOLVENT RESISTANT MEMBRANES FROM POLY-(P-PHENYLENE-TEREPHTHALAMIDE),
Forschungsinstitut Berghof G.m.b.H., Tuebingen (Germany, F.R.).
P. Zschocke, and H. Strathmann.
In: Desalination, Vol 34, Nos 1/2, p 69-76, July-August, 1980 (Comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979). 2 Fig, 4 Tab, 5 Ref.

Descriptors: Separation techniques, *Membranes, *Membrane processes, Polymers, Desalination, *Ultrafiltration membranes, Poly(p-phenylene-terephthalamide polymer.

A new solvent resistant ultrafiltration membrane has been developed from poly-(p-phenylene-terephthalamide), a polymer available from du Pont. This membrane exhibits a water flux of 4,500 1/m super 2 d with a rejection of cytochrome C in excess of 99% at 5 bars. Fluxes from 1,450 to 13,800 1/m super 2 d are observed for common solvents. The membrane is stable in almost all organic solvents including dimethylsulfoxide, n-methylpyrrolidone, dimethylacetamide and others.

PROPERTIES AND LONG-TERM BEHAVIOR OF ION EXCHANGE MEMBRANES,
GKSS - Forschungszentrum Geesthacht G.m.b.H., Geesthacht-Tesperhude (Germany, F.R.). Inst. fuer Werkstofftechnologie und Chemie.
K. Kneifel, and K. Hattenbach.
In: Desalination, Vol 34, Nos 1/2, p 77-96, July-August 1980 (comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979). 7 Fig, 3 Tab, 12 Ref.

Descriptors: *Membranes, *Membrane processes, *Electrodialysis, Water treatment, Wastes, Desalination, Electrolysis plants, *Ion exchange membranes.

Membrane data available in the literature from data sheets of the membrane manufacturers are difficult to compare due to different and at times ill-defined test conditions. The characteristic properties: permselectivity, electrical resistance, ion exchange capacity, and water content of commercial ion exchange membranes were therefore determined under standardized conditions. To obtain information about the useful lifetime and the range of applicability in electrodialysis plants, the membranes were subjected to several chemical environments both at room temperature and at elevated temperatures for periods up to five years. The results obtained should be helpful in selecting the appropriate membranes for different electrodialysis applications such as water desalting, wastewater treatment, and recycling of chemical process solutions.

MORPHOLOGY OF AROMATIC POLYAMIDE TYPE ASYMMETRIC REVERSE OSMOSIS MEMBRANES,
Academia Sinica, Dalian (China). Dalian Inst. of Chemical Physics.
Chen Jiayan, Bi Shuchun, Zhang Xingda, and Zheng Lingying.
In: Desalination, Vol 34, Nos 1/2, p 97-112, July-August, 1980 (Comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 19-19, 1979). 8 Fig, 1 Tab, 21 Ref.

Descriptors: *Membranes, *Reverse osmosis, Desalination, *Membrane processes, Membrane morphology, Scanning electron microscope, Transmission electron microscope, Asymmetric membranes, *Aromatic membranes.

The morphology of aromatic polyamide type reverse osmosis membranes has been investigated with the aid of the scanning and transmission electron microscopes (SEM and TEM). The majority of the samples are treated by the method of critical point drying (CPD) and then observed with a SEM. It has been found that in the dense layer of these asymmetric membranes prepared with significant solvent evaporation, there exists a micellar structure, but various types of defects have been observed on the surface of some parts of such membranes. The variation in structure in the cross-section off these membranes due to different membrane materials and preparation techniques was observed. In the membranes we studied, we found the RO performance to be correlated not only with the degree of densification and reliability of the surface layer but also with the structure of the cross-sections. The cross-section structure characteristics of such membranes with higher RO performance are rather different from those reported in the literature on cellulose acetate and Nomex membranes without notable evaporation. The influence of the casting conditions of the membranes on the morphology is discussed preliminarily.

USE OF THIN CHANNEL SYSTEMS FOR ULTRAFILTRATION AND HYPERFILTRATION,
W. Kofod Nielsen, and R. Frik Madsen.
In: Desalination, Vol 34, Nos 1/2, p 113-130, July - August, 1980 (Comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979). 13 Fig, 6 Ref.

Descriptors: *Membranes, *Membrane processes, Desalination, *Ultrafiltration membranes, *Hyperfiltration membranes, Polarization, Thin-channel systems.

One of the first systems developed for hyperfiltration in the 1960's was a thin-channel system. In the 1970's, a thin-channel system was developed with short channels which proved to be excellent for hyperfiltration as well as for ultrafiltration. A description of the system is given. Examples of the applications of thin-channel systems for concentration at high viscosities and high dry-substance contents, e.g. in the food industries, are given. The theory of thin-channel systems is briefly described, especially in respect to answering to question why thin-channel systems are especially suited for treatment of highly viscous liquids. Concentration polarization is an important factor in determining capacity and membrane-separation properties. The concentration polarization can be calculated theoretically, but is difficult to measure quantitatively. A description of a thin-channel system is given, in which the membrane surface can be seen visually. In such a system, the concentration polarization can be shown visually, using coloured solutions. In this way, the influence of flow and pressure on the concentration polarization can be shown by photographs of the concentration-polarization profiles. A survey of the thin-channel systems on the market today is given.

ULTRAFILTRATION PROCESSES FOR POLLUTION CONTROL AND CHEMICAL REUSE IN THE TANNING INDUSTRY,
Naples Univ. (Italy). Facolta di Ingegneria.
E. Drioli, and B. Cortese.
In: Desalination, Vol 34, Nos 1/2, p 131-140, July - August, 1980 (Comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979). 3 Fig, 5 Tab, 3 Ref.

Descriptors: Separation techniques, Water treatment, Emulsions, Membranes, *Membrane processes, Water purification, Waste disposal, Desalination, Industrial wastes, *Ultrafiltration membranes, Streams recycle, *Tanning industry wastes.

The new regulations which are in force today require that tanning plants study and implement new technique to reduce pollution at costs which are not prohibitive to the economic continuation of the basic tanning process. In this paper, are presented results obtained in ultrafiltration experiments upon two of the most polluting process streams which leave the tannery: the dehairing and the decreasing waste. These results clearly indicate the possibility of solving large part of the pollution problems with ultrafiltration processes and streams recycle.

THE INFLUENCE OF THE POROUS SUBLAYER ON THE SALT REJECTION AND REFLECTION COEFFICIENT OF ASYMMETRIC CA MEMBRANES,
Technical Univ. of Denmark, Lyngby. Inst. for Kemindustri.
G. Jonsson.
In: Desalination, Vol 34, Nos 1/2, p 141-158, July - August, 1980 (Comprising papers on desalination of the Proceedings of the Second Symposium on Synthetic Membranes in Science and Industry, Tubingen, September 17-19, 1979). 10 Fig, 3 Tab, 23 Ref.

Descriptors: *Membranes, *Membrane processes, Reverse osmosis, Desalination, *Cellulose acetate membranes, Salt rejection, Reflection coefficient.

A relation between the reflection coefficient of the membrane skin, sigma sub alpha, and the overall reflection coefficient for an asymmetric membrane, sigma, has been derived. It is shown that the solute permeability for the skin layer, omega sub alpha, and for the porous sublayer, omega sub b, can be estimated from two sets of reverse osmosis experiments. The ratio omega sub alpha to omega sub b varies greatly with the selectivity of the membrane giving a non-linear relation between omega and omega sub alpha. However, the limiting retention, R super (max) and omega sub alpha seem to be fairly equal independent of the pressure level, thus confirming the theoretically derived relation R super (max)= omega sub alpha.

RAYLEIGH-JEFFREYS STABILITY OF THERMOHALINE STRATIFIED FLUIDS SUBJECT TO HORIZONTAL FLOWS,

Technion - Israel Inst. of Tech., Haifa. Energy Lab.
D. Pneuli, and Y. Zvirin.
Desalination, Vol 33, No 2, p 163-184, May, 1980. 2 Fig, 35 Ref.

Descriptors: Desalination, *Desalination processes, Solar ponds, Horizontal flow, *Rayleigh-Jeffreys stability, *Stratified fluids.

The stability of a horizontal layer of a fluid with density stratification due to both temperature and solute gradients, subject to horizontal flow, is studied for different sets of homogeneous boundary conditions. Sufficient conditions for stability, i.e., the maintenance of the original stratification are obtained as the relation between the thermal Rayleigh number, RaT, and the solute Rayleigh number, RaS. A sufficient condition for stability is obtained for all sets of boundary conditions, where PrT and PrS are the thermal and the solute Prandtl numbers, respectively. This condition is, therefore, also applicable in cases where the physical boundary conditions are not well defined, e.g., in practical engineering use of solar ponds.

SOLAR OPERATED, MULTIFLASH DISTILLATION,
Scientific Research Foundation, Jerusalem (Israel).
H. Z. Tabor.
Desalination, Vol 33, No 2, p 221-224, May, 1980. 1 Fig, 4 Ref.

Descriptors: Desalination, *Desalination processes, *Distillation, *Solar operated flash distillation, Multi-stage flash distillation.

The proposal by Gasparini et al of desalination units coupled to solar collectors is criticized. The author shows that the paper contains a number of errors which invalidate its conclusions. There is an apparent confusion of average efficiencies, of mean solar radiation for a heliostatically mounted collector with that for a stationary collector. Also the economic calculations are of little value.

Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113620, Price codes: A05 in paper copy, A01 in microfiche. Completion Report, June 1983. 72 p, 28 Fig, 24 Ref, 3 Append. OWRT C-90015-S(9409)(1), 14-34-0001-9409.

Descriptors: *Electrodialysis, *Electrical impedance, *Fouling, *Membrane, *Polarization, Cleaning, *Desalination, Hyperfiltration, Reverse osmosis.

Electrical impedances of anion-exchange and cation-exchange membranes have been measured in sodium chloride electrolytes under conditions appropriate to desalination by electrodailysis. Alternating-current and Laplace-transformed-pulse methods were used. Results are reported for several membranes under normal desalting current densities, and at high densities causing acid-base formation, with and without presence of a fouling layer. Impedance maxima were found at limiting currents. Under conditions causing substantial concentration-polarization at the membrane diluate interface, a large difference in impedance with measurement frequency was found. Fouling increased low-frequency (diffusion) impedance more than high frequency (resistive) impedance. Measured at 100 Hz, the impedance across an anion-exchange membrane increased substantially at current densities sufficient to cause serious concentration polarization. Measured at 10 KHz very little increase was found. As with the anion-exchange membrane, the impedance at 100 Hz across a cation-exchange membrane increased substantially at current densities sufficient to cause concentration-polarization. However, in contrast with the anion-exchange membrane, the impedance at 10 kHz increased also. The increase of impedance on fouling (with ferric hydroxide) of the cation-exchange membrane was greater.

RESEARCH ON FEASIBILITY OF THIN-FILM COMPOSITE MEMBRANES IN PLATE AND FRAME DEVICES FOR REVERSE OSMOSIS,
FilmTec Corp., Minneapolis, MN.
R. J. Petersen, R. H. Forester, and C. F. Thompson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113703, Price codes: A04 in paper copy, A01 in microfiche. Completion Report, August 1983. 63 p, 15 Fig, 4 Tab, 9 Ref, 1 Append. OWRT C-00196-D(1), 14-34-0001-1407.

Descriptors: *Reverse osmosis, *Economic feasibility, Water treatment, Membrane fouling, *Composite membranes, Plate and frame device, Mississippi River, Minnesota.

The technical and economic feasibility of using plate and frame reverse osmosis systems for low pressure brackish water conversion in conjunction with thin-film composite membranes was investigated. Comparisons were made of membrane fouling rates on Mississippi River water using both FT-30 spiral wound membrane elements and a commercial plate and frame device loaded with FilmTec FT-30 membranes. Both membrane systems exhibited rapid fouling rates at recovery ratios of 50% and higher when run on sand-filtered, pH-adjusted river water. Both membrane systems exhibited approximately the same rates of membrane flux decline due to fouling when examined at comparable recovery rates. The plate and frame system, however, could be restored to its initial flux levels by cleaning treatments, while this was not true for the spiral would elements. For feedwater sources not containing colloidal suspended solids, plate and frame systems were concluded to be economically not feasible based on current cost data. If, however, the feedwater source contained colloidal suspended solids and was known to foul reverse osmosis membranes, certain scenarios favored large plate and frame systems.

Ebasco Services, Inc., New York.
S. J. Senatore.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 3-12, 3 Fig, 6 Ref. (1st Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination process, *Distillation, Vapour compression distillation, Waste heat.

The vapor compression distillation process can be designed as a low capital cost and corresponding low performance ratio (about 7 lbs product per KBtu) or as a higher capital cost and higher PR (about 31) plant. The low PR plant is designed with a maximum brine temperature of about 130F requiring only a polyelectrolyte scale inhibitor. This design would employ a centrifugal compressor that has a pressure ratio of about 1.2. The high PR plant design, which is the subject of this paper, operates at maximum brine temperature of 250F and uses a higher pressure ratio of 1.58. Use of waste heat will be stressed. Either the high or low PR VC process is extremely versatile in application, since it is well adapted to either a dual purpose (power and water) or a single purpose (water only) plant. The high PR that is easily attainable in this design is becoming increasingly more attractive, from an economic view, as the price of fuel continues to escalate. For example, at $5.00/MBTU the fuel contribution to the total cost of water is $5.20/Kgal at a PR of 8 and is reduced to about $1.34/Kgal at a PR of 31. The design and process descriptions for a 2.35 mgd plant will be presented. This plant employs a 65,000 CFM centrifugal compressor. The compressor is driven by a diesel engine and operates across a 4 effect vertical tube foam evaporator. An updated plant cost estimate will be presented and cost of product water.

AN ADVANCED BARGE MOUNTED VTE/VC FOR THE DESALINATION OF SEAWATER,
Envirogenics Systems Co., El Monte, CA.
D. K. Emmermann.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 13-20, 4 Fig, 2 Ref. (1st Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3 1981).

Descriptors: *Desalination, *Distillation, Seawater, Vertical tube evaporator, Vapour compression distillation.

An advanced VTE/VC seawater desalination plant is described. It is a barge-mounted, selfcontained demonstration plant with a rated freshwater output of 5,000/cu m per day and a performance ratio of 30:1 which includes the plant's electrical consumption. Included is a process description of a 24 effect VTE unit with a steam turbine driven compressor and generator combined with two topping effects. Additional features incorporated on the barge include foamy upflow evaporation, ion exchange for seawater pretreatment as well as provision for acid or polymer dosing, and the capability of operation up to a maximum brine temperature of 150C. Test and operational data are presented.
W84-00205

INDUSTRIAL OPERATING EXPERIENCE OF MORE THAN THREE YEARS WITH A 1440 M SUPER 3/DAY SNAMPROGETTI VTE,
Snam Progetti S.p.A., Milan (Italy).
P. Tiraboschi.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 21-28, 4 Fig, 2 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination processes, Multistage flash distillation, *Acids, *Pretreatment of water.

The new desalination process developed by Snamprogetti is discussed and the experiences gained in over 3 years of industrial run is discussed. For two and a half years the plant was fed with acid treated sea water, while in October 1980 it was decided that a high temperature inhibitor, namely Nalco D-4221, should be used. This modification had been envisaged since the beginning as a possibility which, within the programme of research on the desalination unit, could provide an alternative to the acid treatment. The results achieved in over 6 months of this new treatment are good, despite a slight reduction in the thermal exchange coefficients as compared with the results of the acid treatment. An examination of the production diagram shows the good reliability and consequent on stream factor of 94%, which is considerably higher if compared with the 70% of an average MSF plants.

PROCESS SELECTION GUIDE TO SEAWATER DESALTING,
Aqua-Chem, Inc., Milwaukee, WI.
D. R. Finnegan, and W. M. Wagner.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 29-48, 9 Tab, 5 Ref, 6 Fig. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3,1981).

Descriptors: *Desalination, Desalination plants, Distillation, Reverse osmosis.

As desalting technology advances, old processes change and new ones are developed. The current commercial seawater desalting processes including mechanical vapor compression (MVC), thermocompression (TC), multiple effect (ME), once-through multistage flash (MSF-OT), brine recirculation multistage flash (MSF-BR), and reverse osmosis (RO) are compared. These processes are compared on the basis of maintenance and operating complexicity and capital and operating costs. The goal of the paper is to help users and planners answer the question, 'What process is best for me.' Although some of the comments are applicable to all size plants, they are directed primarily to plants less than 2,000,000 GPD capacity. Plants using a combination of processes or hybrid systems are not considered.
W84-00207

COMPARISON OF MSF HEAT REJECTION SECTIONS AND SEAWATER COOLED POWER STATION CONDENSERS,
Watson Desalination Consultants, Manassas, VA.
B. M. Watson, and K. Eimer.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 49-56, 2 Fig., 20 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination processes, Distillation, Multistage flash distillation, *Evaporators, *Condensers, Cooled power station condenser.

A comparison of seawater cooled power station condensers and the heat rejection sections of multistage flash evaporators (MSF) showed very similar design and operational parameters. Remarkable differences are to be seen with regard to the design fouling factor. Typical design fouling factors of MSF rejection sections are about 7 times higher than with a power station condenser. This will result in a heat exchange surface of the rejection section, which is about 50% to 70% larger than with P.S. consensers and will subsequently cause higher capital costs. Design fouling factors much lower than the ones used up to now are recommended.
W84-00208

ADVANTAGES OF THE EJECTOCOMPRESSION PROCESS IN SEA WATER DESALINATION,
Societe Internationale de Dessalement, Paris (France).
M. Lucas, and S. Hessemans.
In: (1st. Volume of the Proc. ofthe Intern. Congress on Desalination and Water Reuse, Bahrain, Nov 29-Dec 3, 1981) Desalination, Vol 38, Nos 1/2/3, November 1981, p 57-63, 2 Fig, 2 Tab.

Descriptors: *Desalination, Desalination process, *Distillation, Multistage flash distillation, Ejecto-compression.

The various techniques were developed by SIDEM for seawater desalination. Among those techniques the vapour compression process by ejectocompression is discussed. The ejecto-compression process has allowed SIDEM to construct packaged type units with rising maximum capacities: 600 cu m/d in 1979, 1,500 cu m/d in 1980, 2,600 cu m/d in 1981. The main characteristics of 1,500 and 2,600 cu m/d units are given and their operating experience of this type of plants are reviewed. Multiflash units of same capacity are compared in terms of investment costs as well as compactness reliability.

THE EFFECT OF AIR ON CONDENSATION ON A ROPED TUBE,
Glasgow Univ. (Scotland).
J. Cunningham, and A. Holmes.
In: Desalination, Vol 38, nos 1/2/3, November 1981, p 65-74, 5 Fig, 2 Tab, 6 Ref. (1st. Vol of Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Distillation, *Heat transfer surfaces, Roped tubes, Plain tubes, *Tubes.

With an increasing interest in the use of enhanced heat transfer surfaces being shown in connection with desalination, experiments have been carried out to compare the effect on different tubes of noncondensable gases. The tests were made on two roped and one plain tube, each tube having a nominal length and inside diameter of 690 mm and 11 mm respectively. Cooling water velocities ranged from 0.8 m/s to 4.2 m/s and bulk air concentrations at inlet of up to 4.25% by weight were investigated. Although the effect of air on the condensation process was greater on the roped tubes at low cooling water velocities, at the velocities commonly associated with desalination plants there was little difference between the effect of noncondensables on roped and plain tubes. This type of fouling is no worse on roped tubes compared to plain tubes.

DESALINATION BY VAPOR COMPRESSION,
Maschinenfabrik Augsburg-Nuernberg A.G., Munich (Germany, F.R.). Abt. Neue Technologie.
W. Bulang.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, 10 Figs. p 85-97 (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Distillation, Vapor compression distillation.

Description of a newly developed desalination plant system is given. The advantages of the new system are mainly: low operating costs, simplicity of the monostage integrated design, and moderate operation temperatures resulting in negligible corrosion and scaling. A high speed high efficient vapor compressor with high volumetric flow is integrated to the vaporator tank. Horizontal heat exchanger bundles with high heat transfer coefficient self-cleaning low erosion film flow are suspended in a cylindrical evaporator tank. Results of operation under various process parameters are presented.

THE EFFICIENT PRODUCTION OF ELECTRICITY AND WATER IN COGENERATION SYSTEMS,
Bechtel Power Corp., San Francisco, CA.
S. K. Tadros.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, 3 Figs, 1 Tab, 6 Ref. p 99-108 (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Distillation, Electric power, Multistage flash, Steam turbine, Cogeneration systems, Power to water ratio.

Two topping cycle steam turbine cogeneration systems are discussed that can be used to simultaneously produce electricity and water. The water desalination plant selected for detailed comparison is the well-known multistage flash (MSF) evaporator cycle which uses brine recirculation and high temperature additives for scale protection at 233F maximum brine temperature. The impact is discussed of expected future fuel prices on the design of the cogeneration systems under consideration and factors which would further improve the thermal efficiency of both power and desalination plants. The fuel chargeable to power (FCP) is determined in two cases: Backpressure turbine/multistage flash scheme and Extraction turbine/multistage flash scheme. The relation between the cogeneration index in kWh per million Btu to the process, steam turbine backpressure, and power to water ratio are discussed.
W84-00212

CENTRIFUGAL PUMPS FOR DESALINATION,
Ingersoll-Rand Co., Phillipsburg, NJ.
F. F. Antunes, R. E. Cornman, and R. J. Hartkopf.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, 4 Figs., 7 Ref. p 109-122 (1st. Vol of the Proc. of the Intern. Congress on Desalination and Wate Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination apparatus, Centrifugal pumps, *Pumps, Brines.

Centrifugal pumps used for desalination require more stringent material selections and different design considerations than normal applications. The liquid being pumped can be seawater, brackish water, or a concentrated brine. The longevity of the pumps in service depend on their design and the materials used as well as the operating conditions present. Four different pumps related to desalination are discussed. These include vertical wet pit intake pumps, reverse osmosis horizontal multistage charge (injection) pumps, vertical can brine recycle pumps, and horizontal pipeline transfer pumps.
W84-00213

REVERSE RUNNING CENTRIFUGAL PUMPS AS HYDRAULIC POWER RECOVERY TURBINES FOR SEAWATER REVERSE OSMOSIS SYSTEMS,
W. A. Raja, and R. W. Piazza.
In: (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981) Desalination, Vol 38, Nos 1/2/3, November, 1981. 8 Figs. p 123-134.

Descriptors: *Desalination, Desalination apparatus, Pumps, Seawater, *Reverse osmosis, Hydraulic power, Recovery turbines.

The application is discussed of reverse running centrifugal pumps as power recovery turbines to recover up to 80% of that energy. The economics of Hydraulic Power Recovery Turbine (HPRT) systems are explored with respect to the equipment cost, operating costs and payouts for the different sizes of RO systems. HPRT's come in various sizes, types and configurations with efficiencies being a function of specific design, flow rate, pressure and speed. Typical design features of HPRT's are described for use in RO system. Different schemes and equipment arrangements are available and require the use of steam turbines, motors, electric generators, clutches, and speed controls or a combination of the above for optimum results. Recommendation of the most economical equipment arrangement for the RO system is discussed.

DESIGN OF HIGH EFFICIENCY SINGLE AND DUAL PURPOSE PLANTS WITH GAS TURBINES,
G. F. Tusel, and I. Kamal.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 135-144, 8 Figs. (1st. Vol of Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Distillation, Multistage flash, Vertical tube foam evaporation, Reverse osmosis, Gas Turbines, Middle East.

Three basic sizes of gas turbines were considered (30.6, 79.4 and 208 MWe output at ISO conditions). Four different processes were considered for the desalination plants: multistage flash (MSF), vertical tube foam evaporation (VTFE), combined vertical tube foam evaporation-vapor compression (VTFE/VC) and reverse osmosis (RO).

MEDA - A NEW THERMAL CONCEPT FOR DESALTING PLANTS,
G. F. Tusel, B. Ohlemann, D. K. Emmermann, and I. Kamal.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 147 (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: Desalination, Desalination plants, *Seawater distillation, VTFE, Vapor compression multistage flash distillation, *Distillation, MEDA project(barge mounted).

The MEDA project comprises a highly efficient, self-contained, VTFE-VC-MSF seawater distillation plant with a capacity of 5000 tons of fresh water per day at a fuel-use performance ratio of 11.8 kg/1000 kJ heat content of fuel. To demonstrate advanced desalting technology with a plant of sufficient capacity in various parts of the world under varying seawater and climatic conditions, MEDA is barge-mounted. Advanced features installed on the barge are: continuous ion exchange pretreatment for removal of calcium and regeneration by brine-blowdown, high heat-transfer rates due to enhanced tubing and foamy up-flow, spirally-indented horizontal tubes in the MSF section, surfactant recovery, turbine driven steam compressor with topping effects, and reverse osmosis system with polishing unit for providing boiler make-up for plant start-up. The calcium removal by ion-exchange permits plant operation with a maximum brine temperature of 150C. Product is redistilled in the MSF cooler to produce high purity distillate for desuperheater injection water and boiler make-up.

PERFORMANCE TESTS ON A VERTICAL TUBE EVAPORATION,
Fachhochschule Cologne (Germany, F.R.).
B. Kunst.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 149 (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Vertical tube evaporator, *Distillation, Foaming agents.

A two-effect evaporator with a rated capacity of 10,000 l/d has been designed for measuring heat transfer coefficients, pressure drops, entrainment rates and scaling behavior in upflow and downflow VTE. The evaporator is in a closed loop system. The temperature operating range extends from 45 to 145C. Foaming agent added to the sea-water is continuously recovered from the blow down in an extraction column. The performance of the two VTE effects is measured in dependence of temperature, brine flow, salt and foaming agent content.

IN SITU CORROSION STUDY OF STAINLESS STEELS IN AN MSF DESALTING PLANT,
Uddeholms A.B. Degerfors Jarnverk (Sweden).
S. Nordin.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 151 (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Corrosion, Multistage flash distillation, Stainless steel.

The corrosion resistance of different stainless steel grades have been studied as regards localized attack under service conditions. Test racks with welded samples with artifically applied crevices were inserted in three different flash chambers. Materials used for splash plates, brine piping, and condensor tubes were also tested. Being a pilot plant, various process conditions were tested. Hence, the materials have been exposed to different corrosive conditions, including stagnant seawater during shut-down periods. Stainless steels of type 316L and higher alloyed exhibit good corrosion resistance, even in brine at high temperature via pipes from the brine heater.

A TUBELESS EVAPORATOR,
Schroeder Process Corp., Santa Ana, CA.
D. W. Schroeder, and P. J. Schroeder.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 155 (Abstract only)(1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Direct contact evaporation, Tubeless evaporator.

A direct contact evaporation process was developed for desalination and waste concentration which can include by-products recovery. The process uses a working substance (WS), such as a high melting organic compound, at its freezing point, to effect the direct contact evaporation. An acceptable WS must be insoluble in water, inert and easily separated by specific gravity difference from brine, product water, and any solids produced. It is also desirable that they be non toxic, non flammable, cheap, and have a high heat of fusion. Several WS's were identified with potential to be used in a commercial plant. A WS screening program tested melting range, solubility, tendency to entrain or emulsify, and stability, in a laboratory program. The bench-scale-plant program simulated the operation of major pieces of equipment with WSs that passed the screening program, and seawater and other saline waters.

FOAM CONTROL ADDITIVES IN MSF DESALINATION,
Pfizer Central Research, Groton, CT.
M. H. Auerbach, J. J. O'Neill, R. A. Reimer, and S. W. Walinsky.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 159-168, 5 Figs, 2,Tab, 26 Ref.

Descriptors: *Desalination, Desalination plants, *Multistage flash distillation, *Foam control additives, Polyglycol monoalkyl ethers, FLOCON anti-foam AF-4.

Excessive foaming in multistage flash desalination plants can give rise to salt contaminated distillate and reduced operating efficiency. Plant operating variations in pressure, temperature, flow and seawater feed composition and alkalinity can perturb vapor/liquid equilibria, resulting in increased levels of foam. Since such foaming is not always controlled by mechanical means, additives are often needed to control foaming level. In additing to controlling foam, a useful additive must not interfere with heat transfer or with the performance of the scale control additive; it must not contain steam-volatile components that can contaminate the distillate; it must be stable at KSF operating temperatures and residence times; and it should be compatible with the antiscalant feed solution. Antifoam performance data for over 60 candidates in 7 chemical classes were determined according to these criteria. The most effective structural class was found to be the polyglycol monoalkyl ethers. Foam control effectiveness within this class was shown to be a function of ethylene oxide content and alkyl chain length. The most effective additive found is offered commercially as FLOCON Antifoam AF-4. FLOCON AF-4 has been used successfully in high-temperature MSF plants.

TARANTO DESALINATION PLANT: A COMPARISON BETWEEN THEORETICAL AND ACTUAL PH VALUES IN A CORRECT DESIGN ACID TREATMENT PLANT,
Italimpianti S.p.A., Genoa.
S. Arazzini, R. Borsani, G. Migliorini, and P. Bozzini.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 185-199, 6 Fig, 1 Tab, 10 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Distillation, *Hydrogen ion concentration, *Italy, Taranto, Acid treatment plant.

The problem of increasing reliability of acid treatment plants was tackled by ITALIMPIANTI with satisfactory results in 3 steps: (1) Theoretical calculation on pH optimum optimum distribution through the plant, adopting the accepted theory of CO sub 2 hydrolysis and HCO sub 3 equilibria in sea water. Also practical values in the Debye-Huckel equation are used in worked examples. (2) By correct positioning of chemical injection points and pH meters arrangement. (3) By correct sizing of decarbonating tower and degasifier which play a key rule in the success of acid treatment. This philosophy was applied in the 5th desalination plant which ITALIMPIANTI designed, built and put into operation in April 1980 for ITALSIDER at TARANTO Steel Works. Correct design enabled achievement of contract performance guarantees. A brief description of the technical features of the plant, the main parameters and the guide concepts of an easy acid treatment design are reported together with the same operational data collected during last year showing the stability and reliability of the system.

ENERGY CONSUMPTION AND OPERATIONAL ASPECTS OF ON LOAD BALL CLEANING SYSTEMS,
K. Eimer.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 201 (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Distillation, Evaporators, *Multistage flash distillation, *Load ball cleaning systems.

On load sponge ball cleaning systems have been proved to remove brine side fouling, maintain high heat transfer rates and high performance of MSF evaporators. Besides capital costs, service, and costs for sponge balls, the energy consumption of the system has to be taken into account. Energy consumption is influenced by hydraulic and exergetic losses of the system. Especially the exergetic losses of the system by recirculating the balls with hot or cold water influence the energy consumption considerably. With unfavourable conditions the continuous hot water recirculation from the

brine heater outlet to the coldest recovery stage increases the heat consumption by as much as 5% with a 22,000 cu m /d MSF. Specially designed ball recirculation systems bring this heat loss down to negligible values. Besides the energy consumption the operational aspects of the different ball recirculation systems have been evaluated.

STRUCTURE/PERFORMANCE RELATIONSHIPS OF HIGH-TEMPERATURE MSF SCALE CONTROL ADDITIVES,
Pfizer Central Research, Groton, CT.
S. W. Walinsky, B. J. Morton, and J. J. O'Neill.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 203 (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Distillation, *Scaling, *Multistage flash distillation, Structure, Performance.

Low molecular weight polymers (MW sub w = 500-10,000) of maleic, fumaric, itaconic, methacrylic, acrylic, and vinylsulfonic acid were prepared and evaluated as high temperature alkaline scale inhibitors. Suppression of valcium carbonate and magnesium hydroxide scale was measured in a laboratory single-stage flash evaporator (120C) and the results compared with the performance of monomeric inhibitors such as amino and hydroxyphosphonates and phosphonocarboxylates. Some critical properties which contribute to scale control were also investigated - including the ability of these additives to inhibit crystal growth, to disperse or suspend alkaline precipitates, and to remain soluble in concentrated seawater over a range of temperatures. The relationship between the alkaline scale control performance of the various additives and their chemical structure, molecular weights and degree of ionization is discussed.

PRESENT TRENDS IN MATERIALS SELECTION AND PERFORMANCE IN MULTISTAGE FLASH DESALINATION UNITS,
Little (Arthur D.), Inc., Cambridge, MA.
J. D. Birkett, and E. H. Newton.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 207-222, 8 Figs, 11 Tab, 9 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Materials testing, Multistage flash distillation.

Data is utilized from a series of worldwide surveys conducted from 1968 to 1980 for the U.S. Department of the Interior, Offices of Saline Water and Water Research and Technology as well as the recent literature to illustrate the improvements made in the materials selection process over the last several years. Trends in materials used for heat exchange tubing, flash chambers and components, pumps, water boxes, etc., are enumerated and evaluated with respect to likely service life as a function of the severity of operating conditions. Plant factor (percent of time operating at rated capacity) is correlated with design and to gain perspective is compared to plant factors achieved in the chemical processing industry generally. Present trade-off decisions with respect to materials, operating temperatures and conditions, performance factors, electrical energy consumption, and use of chemicals are summarized and commented upon.

SEA WATER INTAKE AND ITS EFFECT ON HEAT REJECTION DESIGN AND MATERIAL FOR FLASH DISTILLATION PLANT,
M. H. A. El-Saie, M. S. I. Kafrawi, and A. K. T. A. Karim.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 257-267, 3 Figs, 7 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Seawater, Distillation, *Multistage flash distillation, Jetties, Settling basins, *Suspended solids, Pretreatment of water.

The suspended matter in sea water plays a big role in the design of seawater intake and heat rejection section. The seawater intake usually depends on the shore nature and water quality. Chemical treatment can handle marine growth and bacteria but the suspended matter in the seawater needs further treatment usually by settling basin and screens, these are normally costly and need a minimum plant size to be economical. For relatively small installation of up to about 15 MGPD plant, other solutions can be adopted in the seawater design and the choice of materials for the heat rejection section. For a seawater intake of up to 30,000 or 40,000 cu.m./hour for a desalination plant with a large variation of temperature between summer and winter and suspended mattter in a certain range and sizes of grain, it is more economical to have a jetty with a pressurized rotary screen and titanium tube for the heat rejection section instead of settling basin and copper nickel tubes and seawater recirculation. This will save at least 2% of the total cost of the plant. Also the execution of seawater intake with jetty is much quicker than with a settling basin.

Descriptors: *Desalination, Desalination plants, Membranes, *Reverse osmosis, Hollow fibers, B9 fiber bundle performance.

Measurements of the pressure drops along the bores of hollow fibers in a B9 fiber bundle have been made under operating conditions. A theoretical model of the fiber behaviour is presented and analyzed. An analytical solution is obtained for the case of a fiber in a uniform crossflow of brine of uniform concentration and uniform pressure. A numerical procedure, making use of this analytical solution, is developed to solve the more general problem of detailed bundle behaviour. This procedure takes into account the variation of brine concentration along fiber lengths and the fact that in some cases the product concentration can be significant. Sets of experimental data, including the measurements of bore pressures, are presented and analyzed using a computer program based on the numerical procedure presented. Evidence of compression of the fiber bore diameter due to the external brine pressure is found, particularly at higher temperatures and pressures.

A PHYSICOCHEMICAL APPROACH FOR THE CHOICE OF POLYMERIC MEMBRANE MATERIALS FOR WATER DESALINATION BY REVERSE OSMOSIS,
National Research Council of Canada, Ottawa (Ontario). Div. of Chemistry.
T. Matsuura, Y. Taketani, and S. Sourirajan.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 319-337, 3 Fig, 7 Tab, 16 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Reverse osmosis transport, Fouling, *Polymeric membranes, Interfacial water layer.

Interfacial properties such as the thickness of interfacial water layer, the distribution coefficient of solute between interfacial and bulk water phases, and the volume of interfacial water per unit mass of polymer material have been identified as relevant physicochemical quantities governing reverse osmosis transport and determined by gas and liquid chromatography methods with respect to different polymeric membrane materials. They are further split into the contribution from the structural component of polymer repeating unit. Force constants A and D for sodium chloride, representing the repulsive force working between membrane surface and solute, have been calculated on the basis of interfacial properties obtained above. Using these forces constants, the pore sizes required to achieve 99.9% of sodium chloride separation are obtained for different polymeric membrane materials. Furthermore, the prediction procedure for the effect of preferentially adsorbed organic molecules on the separation of sodium chloride and product rate is illustrated as a model for 'fouling' in the desalination process by reverse osmosis.

PREDICTING FLUX DECLINE OF REVERSE OSMOSIS MEMBRANES,
Keuringsinstituut voor Waterleidingartikelen, Rijswijk (Netherlands).
J. C. Schippers, J. H. Hanemaayer, C. A. Smolders, and A. Kostense.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 339-348, 5 Figs, 1 Tab, 4 Ref (1st. Vol of the Proc of the Intern Congress on Desalination and Water Reuse, Bahrain, Nov 29-Dec 3, 1981).

Descriptors: *Desalination, Desalination plants, *Reserve osmosis, Mathematical model, Membrane processes, Ultrafiltration membranes.

A mathematical model predicting flux decline of reverse osmosis membranes due to colloidal fouling has been verified. This mathematical model is based on the theory of cake or gel filtration and the Modified Fouling Index (MFI). Research was conducted using artificial colloidal solutions and a pilot plant equipped with ultrafiltration membranes. Polystyrene latex spheres, having a size of about 0.05-0.08 mu m were used as a foulant. The

measured and calculated values of flux of the ultrafiltration membranes decline as a function of time and agree reasonably well. The difference between the measured and calculated values may be explained by the assumption, that initially blocking filtration occurs instead of cake or gel filtration.

FORMATION OF ASYMMETRIC CELLULOSE ACETATE MEMBRANES,
Technische Hogeschool Twente, Enschede (Netherlands). Dept. of Chemical Technology.
H. Bokhorst, F. W. Altena, and C. A. Smolders.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, 8 Figs, 14 Ref, p 349-360 (1st. Vol of the Proc of the Intern Congress on Desalination and Water Reuse, Bahrain, Nov 29-Dec 3, 1981).

Descriptors: *Desalination, Desalination plants, Membranes, *Reverse osmosis, Cellulose acetate.

Cellulose acetate membranes were prepared from casting solutions containing dioxane as a solvent and varying concentrations (up to 6%) of maleic acid as an additive. Coagulation took place in water at different temperatures. The effect of these variables on membrane structure and membrane properties is related to two phenomena of phase separation in the system cellulose acetate/dioxane/water with gelation in the top layer and liquid-liquid phase separation in the sublayer of the membrane. A solution transport model is adopted which correlates membrane flux with the skin thickness and membrane salt rejection with the compactness (microstructure) in the skin. Effects of variables such as maleic acid concentration and coagulation temperature on the position of curves in the phase diagram and on membrane properties are discussed.

HOLLOW FINE FIBER VS. FLAT SHEET MEMBRANES - A COMPARISON OF STRUCTURES AND PERFORMANCE,
Du Pont de Nemours (E.I.) and Co., Wilmington, DE.
J. K. Beasley, and R. E. Penn.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 361-372, 6 Fig, 24 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Membrane processes, *Polymers, Hollow fiber, Membranes, Flat sheet.

The reverse osmosis performance of polymeric membranes depends not only on the chemical structure of the polymer but also on the physical structure of the membrane. Percolation theory is used to describe water flux and salt passage as functions of the polymer density, or porosity, of the membrane. Water permeability increases with increasing porosity, or decreasing polymer density in the membrane. Salt passage is controlled primarily by the membrane polymer density in the surface layer on the feed side of the membrane. Experimental data on both hollow fine fiber and flat sheet membranes are consistent with the basic concepts of percolation theory.

PURIFICATION OF HIGH TEMPERATURE WATER BY THE REVERSE OSMOSIS PROCESS,
Tokyo Univ. (Japan). Inst. of Industrial Science.
S. Kimura, and T. Nomura.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 373-382, 11 Fig, 3 Ref. (1st. Vol of the Proc of the Intern Congress on Desalination and Water Reuse, Bahrain, Nov 29-Dec 3, 1981).

Descriptors: *Desalination, Desalination plants, *Reverse osmosis, Membranes, Water treatment, Hollow fiber, 'Hollosep', Brines.

For the high temperature desalination and purification possible use of two kinds of membranes was pursued. A dynamically formed membrane is fundamentally usable at high temperature, and a module was developed and tested. A commercially available module, hollow fiber type 'Hollosep', was found durable over 70C at 30 kg/sq cm. These modules were tested by treating the geothermal brine, that contained SiO sub 2 and NaCl. They worked well when the brine contained only ionic SiO sub 2, but was fouled by the colloidal SiO sub 2.

AN INVESTIGATION OF USING STATISTICALLY DESIGNED EXPERIMENTS AND A COMPUTER MODEL,
Florida Inst. of Tech., Melbourne. Dept. of Mechanical Engineering.
A. M. El-Nashar, and J. S. Shih.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 397 (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Membranes, *Desalination, Model studies, Computer models, Membrane formation parameters.

The results are outlined of an experimental program aimed at establishing the best formation parameters for dynamic Zr(IV)-PAA membranes formed on porous ceramic supports. Parameters investigated are: pressure, circulation velocity, Zr(IV) concentration, and PAA concentration. Twenty statistically designed experiments were conducted to evaluate the effect of these four parameters on the flux and rejection of the resulting membrane at the end of the formation procedure. The results were used in a multiple linear regression computer program BMD-PIR, which develops the measured values with an accuracy of plus or minus 2%. Using these models, it is possible to form a membrane with a given value of flux or rejection within their ranges. For the range of variables used in this study, the maximum membrane rejection was 91%, corresponding to a flux of 10 gpd/ sq ft (1.7 cm/hr) for 0.05 M NaCl and 800 psi (5.4 MPa). High rejection was obtained by increasing the membrane formation pressure and by increasing the PAA concentration. High flux can be achieved by increasing the formation pressure, by increasing the Zr(IV) concentration - up to 9.0 x 10 super -4M super -, and by increasing the circulation velocity.

THE PERFORMANCE OF THE 12,000 M SUPER 3/DAY SEAWATER RO PLANT AT JEDDAH, SAUDI ARABIA,
Florida Inst. of Tech., Melbourne. Dept. of Mechanical Engineering.
A. M. El-Nashar, and I. Kutbi.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 399 (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: Desalination, Desalination plants, Seawater plant, Reverse osmosis, Jeddah, *Saudi Arabia, Special wound elements.

The performance is outlined of the 12,000 cubic m/day seawater RO plant at Jeddah, Saudi Arabia, which started operation in February 1979. The feedwater has a 42,000-ppm TDS and a maximum seawater temperature of 32C. A first stage includes nine units, eight operating and one stand-by, and a second stage contains three units. The nine first stage and the three second stage RO units are each composed of 56 Fiberglass pressure tubes (Model 66 FRP-6) 150-mm diameter by 6.5 m long, each containing six spiral wound elements manufactured by UOP Fluid Systems Division. The plant uses Fluid System's polyamide thin film composite membrane element, Model 1501 TFC. The pretreatment is composed of dual media filtration, acid injection, sodium hexametaphosphate injection and cartridge filtration.

G. E. Bettinger.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, 3 Figs., 4 Ref. p 419-424 (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, *Desalination plants, *Reverse osmosis, Biological fouling, Permasep B-9 super (R).

A plant, built in 1972, has a total of 24 permeators operating in 4 blocks which are reject staged 4:2. The feed water TDS is 475 milligrams per liter and the silt density index (SDI) after pretreatment is less than 3. Feed pressure is 400 psig and product pressure 10 psig, with an interstate pressure drop of 35 psig. The plant operates at a feed temperature of 20C and an overall conversion of 70%. The product is used for boiler feed and chemical process water. Since its inception this plant has exhibited a problem in maintaining the design product flows and the operating conditions evolved such that two banks of permeators operated for one week, and then a citric acid, formaldehyde cleaning procedure was used on the two banks the second week. The other two banks of Permasep super (R) units, which had been cleaned and sterilized the week before, were then used. The plant was able to operate under these conditions but the cost of manpower and cleaning chemicals required to maintain satisfactory product water flow and quality was excessive.

Descriptors: *Desalination, Desalination processes, Seawater, Pretreatment, *Reverse osmosis, *Coagulation, Hydrogen ion concentration, Coagulation-filtration.

The effect of pH of the filtrate on the head loss in the inline coagulation-filtration for the pretreatment of reverse osmosis seawater desalination was

investigated. The experiment was carried out using a double media filter with aluminum sulfate as a coagulant. The filtration characteristics were dependent on the pH of the filtrate. The rate of elevation in the head loss and the amount of suspended particles in the filtrate decreased with an increase in the pH, over the range of experimental conditions. The results were briefly considered in relation to the deposit morphology of suspended particles on the surface of the filter grain.

Descriptors: Desalination, Desalination plants, Reverse osmosis, Membrane processes, 'Hollosep', Salinity, Seawater.

Two types of new 'HOLLOSEP' have been developed for single-pass desalination of high salinity seawater. One is a high pressure and high temperature module, type 'HPT'. The performance of this new type HOLLOSEP is analyzed in the case of desalination of high salinity seawater under a high pressure of 75kg/sq cm G at high temperature of 40C. The operation costs can be reduced by this high pressure and high temperature operation system. The other is a large size module containing five elements of 12 inches diameter, type 'JM-12'. This module has been developed to reduce the water cost by enlarging the diameter and the length of a vessel coupled with the improvement in water flux rate of the hollow fiber membranes. The fresh water productivity of this module is 150 cu m/day under the conditions of 3.5% NaCl feed water, 30% product water recovery at 55kg/sq cm G.

PIEZODIALYTIC TRANSPORT ACROSS CHARGE-MOSAIC MEMBRANES,
Wroclaw Technical Univ. (Poland). Inst. of Environmental Engineering.
G. Blazejewska-Wisniewska, and T. Winnicki.
In: Desalination, Vol 38, Nos 1/2/3, p 461-471, 9 Fig, 7 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination plants, Anion-exchange, *Membrane processes, Piezodialysis, Mosaic membranes.

The highest concentrations are obtained for symmetric electrolytes and membranes of the second series. When the capacity of the anion-exchange resins in those membranes increases, so does the concentration of the solutions. In second-series membranes the influence of ionic polarization was the least as compared to the remaining two series. All of the membranes under study permit concentration of asymmetric electrolytes only at an initial concentration of 0.05 kmol/cu m. Retention of bivalent ions by charge-mosaic membranes seems to be promising in that it suggests the possibility of separating bivalent from monovalent ions. The optimum parameters at which the concentration effects were the highest, are the following: pressure, 11.3 MPa; initial concentration of the electrolyte, 0.05 kmol/cu m.

THE FT-30 SEAWATER REVERSE OSMOSIS MEMBRANE-ELEMENT TEST RESULTS,
FilmTec Corp., Minneapolis, MN.
R. E. Larson, J. E. Cadotte, and R. J. Petersen.
In: Desalination, Vol 38, Nos 1/2/3, p 473-483, 6 Figs, 1 Tab, 4 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Desalination apparatus, *Reverse osmosis, *Membranes, Thin-film composite, FT-30.

A thin-film composite reverse osmosis (RO) membrane has been developed that provides excellent performance when used in single-pass seawater systems. This membrane, designated FT-30, gives superior performance in such areas as flux, salt rejection, chemical stability, and microbiological resistance. In addition, it is resistant to some oxidizing disinfectant agents, although it is not fully resistant to chlorine; elements fabricated from the membrane have shown damage after 2,000 to 2,500 hours exposure to seawater at 0.5 milligrams per liter (mg/l) active chlorine. The membranes can operate continuously at active chlorine concentrations below 0.2 mg/l. Several long-term studies were carried out at the OWRT Wrightsville Beach Test Facilities. In actual trials in seawater systems, salt rejections as high as 99.5% and fluxes of 23 gfd have been obtained when tested at 800 psi and 25C. Some of the elements have been in continuous operation for over 4,000 hours with no deterioration in salt rejection and with only the normal flux decline usually associated with compaction and scaling. Other elements have been installed in small seawater systems with normal intermittent use for almost two years with no serious loss in performance.

BUILDING AND COMMISSIONING THE 3.0 MGD SEAWATER RO PLANT FOR KEY WEST, FLORIDA,
Water Services of America, Inc., Milwaukee, WI.
W. W. Boesch.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 485-496, 11 Figs. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Reverse osmosis, Membrane processes, Key West, Florida, Seawater.

The fast deliveries and the reliability of a seawater reverse osmosis plant has been demonstrated. The performance of a large plant using the hollow fiber polyamide membranes shows that good potable water can be obtained through a single pass design rather than the more costly two pass design. The comparison between thermal plants and seawater RO points up large contrasts in simplicity of design, compactness, delivery time, reliability and cost.

DESALTING 36,000 PPM WELL WATER WITH ELECTRODIALYSIS - A 5-YEAR REPORT,
Ionics, Inc., Watertown, MA.
H. C. Valcour, Jr., and K. D. McElhinney.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 529-536, 2 Figs, 2 Tab, 1 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Manama, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Electrodialysis, Anion membranes, Well water.

The 36,000-ppm TDS well water is saturated with calcium sulfate and contains high levels of hydrogen sulfide (reported as high as 190 ppm). The 42,000-USGPD plant has now been in service for nearly 5 years and has never failed to provide the potable water needs of the desert camp that it serves. The operation of the pretreatment section of the plant has been modified to reduce the amount of lime fed to the solids contact clarifier, thereby reducing the quantity of acid required for pH reduction of the feed water. The only major modification to the ED portion of the plant has been the installation of new type anion membranes. The membrane stacks are now primarily equipped with two types of anion membranes, both of which operate at a lower electrical resistance and higher ion transfer efficiency. The result of these more efficient anion membranes is a lower power consumption and higher production rate. Improvements to the electrode system have resulted in continuous membrane stack operating periods of over 6000 hours between disassemblies.
W84-00255

TREATING BAHRAIN ZONE C GROUNDWATER USING THE EDR PROCESS,
Ionics, Inc., Watertown, MA.
D. F. Brown.
In: Desalination, Vol 38, Nos 1/2/3, p 537-547, November 1981, (1st. Vol of the Proceedings of the International Congress on Desalination and Water Reuse, Manama, Bahrain, November 29-December 3, 1981). 3 Tab, 3 Fig, 3 Ref.

Descriptors: *Desalination, Desalination plants, *Electrodialysis, Desalination apparatus, Membrane processes, Bahrain, Electrodialysis reversal.

Developing and applying efficient water desalination technologies for treatment of Zone C groundwater appears to be an essential factor in maintaining an adequate water supply for the Island of Bahrain. The quality of this source (11,000 ppm TDS) will increase capital and operating costs of

desalting systems as compared to units currently operating on the Zone B brackish water sources. Conceptual design studies have shown that EDR is directly applicable to Zone C desalination requirements. Pertinent operating characteristics are reviewed of the Mediterranean installation and estimated operating parameters and costs for Bahrain Zone C water treatment are projected. Factors contributing to the improvement in EDR system operating efficiency which make treatment of the Zone C type water feasible are: new aliphatic membranes which improve electrical efficiency, a special electrode Clean-In-Place system which reduces acid consumption for periodic stack cleaning, and a new time phased rversal system which increases efficiency of polarity reversal in multistage units needed to desalt 10-12,000 ppm TDS feed waters. The EDR process offers an attractive, economical alternative for the Zone C desalination requirements.

PARAMETRIC TESTS OF AN ELECTRODIALYSIS REVERSAL (EDR) SYSTEM WITH ALIPHATIC ANION MEMBRANES,
Ionics, Inc., Watertown, MA.
D. Elyanow, R. G. Parent, and J. R. Mahoney.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 549-565, 3 Figs, 4 Tab (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Manama, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Electrodialysis, Desalination apparatus, EDR, Roswell Test Facility, Aliphatic anion membranes, Aquamite X EDR.

During 1980, parametric studies were performed to compare the performance of aliphatic anion membranes to standard anion membranes in an electrodialysis reversal (EDR) system. An Ionics AQUAMITE X EDR unit was used to desalt a high sodium chloride, 4100 mg/l TDS feed water. During these tests, the product salinity averaged 388 mg/l at an average production rate of 25,800 USGPD. The use of aliphatic membranes reduced the desalting energy consumption from 8.1 kwh/kGal with standard membranes to 6.8 kwh/kGal with aliphatic membranes at 75% recovery and, at 92% recovery, from 14.6 kwh/kGal for standard membranes to 11.0 kwh/kGal for the aliphatics. Slightly higher water recoveries were also possible with the aliphatic membranes as they exhibited less water transfer. A maximum recovery of 94% was obtained without operational problem despite calcium sulfate (gypsum) supersaturation levels of up to 165% in the waste stream. The following characteristics are desirable for an EDR plant to treat a high sodium chloride 4100-ppm water: (1) Aliphatic anion membranes for reduced energy consumption, (2) Separate feed for brine and electrode flows for nearly complete recovery of a limited higher quality brackish water source, and (3) 30-minute reversal cycle to improve production and increase recovery.

Descriptors: *Desalination, Desalination plants, Desalination apparatus, *Reverse osmosis, Electrodialysis.

In the RO desalination of sea water with salt contents in excess of 4.0% TDS, a two-stage procedure is necessary today to guarantee reliable, longterm operation and satisfactory product water quality. In general, in a two-stage plant, the salt concentration of the sea water is reduced to about 2000 to 4000 ppm in the first stage and to less than 500 ppm in the second stage. The advantages of the two-stage over a one-stage system are high reliability and possibly lower costs.

ENERGY-SAVING ELECTRODIALYZER FOR SEA WATER DESALINATION,
Tokuyama Soda Co. Ltd. (Japan).
T. Mizoue, Y. Takasaki, Y. Tani, S. Urabe, and E. Asada.
Desalination, Vol 38, Nos 1/2/3, November 1981, p 583 (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Manama, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Desalination apparatus, *Electrodialysis, Seawater, Skid-mounted electrodialyzer.

An energy-saving skid mounted electrodialyzer was developed for sea water desalination. This equipment is suitable for making fresh water for drinking and industrial use. To desalinate 25C sea water and turn out one ton of product water. This equipment consumes only 8.5 KWH of electricity and 0.09 Kg of concentrated sulphuric acid. Low energy consumption is achieved by adoption of low electric resistance membranes, new spaces and new designed one pass type system. Low running cost, easy maintenance and low initial installment cost place the equipment good position in the desalination field. And also we applied high temperature electrodialysis up to 50C of sea water and get figure 6.0 KWH for one ton of product water.

WATER REQUIREMENTS OF AN INLAND NUCLEAR POWER STATION, ENGINEERING AND ECONOMIC ASPECTS,
Israel Electric Corp. Ltd., Haifa.
A. Beck, and M. Schaal.
Desalination, Vol 40, Nos 1/2, January 1982, p 19-24, 2 Tab, 4 Ref.

Descriptors: Water requirements, *Desalination, *Nuclear Powerplants, Engineering, Economic aspects, *Israel, Cooling towers.

Water requirements for construction and operation of a 950 MWe nuclear power plant are estimated. For the bulk of water needed, i.e. condensor cooling, quantities assessed are 12.5 million cu m/year for sea water and 35 million cu m/year for fresh water. Breakeven water costs are calculated below which use of wet cooling towers is more economical than dry cooling towers. Desalinated water costs (70 cents/cu m) are lower than breakeven costs ($1.42/cu m) i.e. it is likely to be more economical to desalt water using some form of wet, rather than dry, cooling towers. It is even more economical to use sea water makeup without desalination but with proper design and choice of materials for cooling towers.

WATER RESOURCES IN ISRAEL AND THE NEED FOR DESALINATION,
Ministry of Agriculture, Tel-Aviv (Israel). Water Commission.
M. Ben Meir.
Desalination, Vol 40, Nos 1/2, January 1982, p 15-18.

Descriptors: *Desalination, Seawater, *Water resources development, Water policy, Planning, *Israel.

Considering the various factors involved in determining timing for introduction of seawater desalination in Israel and the desirable scope, it is presently assessed that a 50-100 MCM/yr desalination plant should operate by the end of the century. The appropriate timing for the introduction of seawater desalination in Israel, and the scope of such operations, can be determined only after due consideration of the following topics: (1) climatic conditions, (2) hydrological situation, (3) possibilities for water resource development, (4) macroeconomic implications of water shortage, (5) the planned geographic and demographic distribution of the population, (6) physical planning in the light of national and social goals, (7) the need to ensure food supplies, and (8) water in relation to the geopolitical situation.

WATER FROM FOSSIL AQUIFERS AS A POTENTIAL SUPPLY SOURCE FOR SOLAR DESALINATION PLANTS ON A REGIONAL SCALE,
Ben-Gurion Univ. of the Negev, Sde Boker (Israel). Jacob Blaustein Inst. for Desert Research.
A. Issar, and G. Oron.
Desalination, Vol 40, Nos 1/2, January 1982, p 25-32, 1 Fig, 8 Ref.

Descriptors: *Water supply, *Desalination, Desalination plants, *Solar desalination, *Israel, Hydrogeology, Hydrogeochemistry.

Studies of the hydrogeology and hydrogeochemistry of the water in the Judea Kurnuk and Arad Group aquifers in the Negev (Cenomanian, Lower Cretaceous and Jurassic) reveal that under a large area of the Negev an aquiferous section 1000- to 1500-m thick is saturated with brackish water. Data derived from oil and water wells enabled the mapping of the various water groups which in turn made it possible to map the chemical composition of the water in the different regions. The potential quantities of water, from the point of view of storage, are in the order of hundreds of billions of cubic meters. Annual pumping amounts, however, are a function of management policy. The annual pumping potential for the next 30 years from the Kurnub Group (Lower Cretaceous) is about 60-100 million cu m, with an allowance of 20-100 m for the reduction of head. The cost of desalination may be reduced if one takes water whose salinity is a little above the threshold of direct application for agricultural use and mixes it with the distilled water supplied by the solar distiller. The chances of achieving even lower costs for distilled water are promising as the water pumped has an average temperature of 40C. Thus, the efficiency of the solar stills may be greater, and may even enable night distillation to take place. The application of solar distillation thus appears promising in the Arava, where the special climatic conditions give a marginal benefit value of $1.00 p/cu m of water for winter vegetables.

PRESENT AND FUTURE ENERGY ASPECTS IN VC, MED SINGLE AND DUAL PURPOSE DESALINATION PLANTS,
Israel Desalination Engineering Ltd., Tel-Aviv.
J. Weinberg, and U. Fisher.
Desalination, Vol 40, Nos 1/2, January 1982, p 49-61, 2 Fig, 8 Tab, 3 Ref.

Descriptors: *Desalination, Desalination plants, Distillation, *Vapor compression, *Multieffect distillation, Heat transfer.

The specific energy consumption as well as investment for present vapour compression (VC) and multieffect distillation (MED) processes are demonstrated. Power consumption for coal dual-purpose stations is 6.5-7.4 kWh/cu m, while for nuclear stations it goes down to 5.1-6.1 kWh/cu m. Improvements in heat transfer and other future modifications may lead to even lower values, i.e., 5.5-6.4 kWh/cu m and 4.4-5.4 kWh/cu m in case of nuclear dual-purpose stations. The cases of VC and single-purpose MED plants are discussed as well. Efficient VC units which use waste energy produce water with energy demand of 8 kWh/cu m. The role that capital costs play in the evaluation of plant expenses is discussed too. In plants where aluminium heat transfer tubes are installed, the fraction of energy used for aluminium production out of the total investment will remain stable, because of improvements in aluminium manufacturing processes. Enhanced heat transfer surfaces with inexpensive additional modifications should be developed. It is worthwhile to check the extension of a VC process which is prefered over MED single-purpose plants for up to 2-mgd enterprises.

AVAILABLE ELECTRICITY LOSS FOR LOW GRADE HEAT,
Israel Electric Corp. Ltd., Haifa.
M. Schaal.
Desalination, Vol 40, Nos 1/2, January 1982, p 77-85, 4 Fig, 5 Ref.

Descriptors: *Desalination, Electric powerplants, Dualpurpose plants, Turbines, Specific energy demand.

A method was developed calculating loss of available electricity production caused by elevated back pressures used in dual purpose powerplants. The method is based on practical data provided by turbine manufacturers. The method is applied to calculate specific energy demands for desalinated water. It is assumed that the steam is supplied from turbine exhaust to desalination plant at a moderate pressure of 12 in of Hg sub (abs).
W84-00264

COST OF MARGINAL ENERGY CHARGEABLE TO DESALINATION IN THE ISRAEL ELECTRIC CORP. GENERATING SYSTEM,
Israel Electric Corp. Ltd., Haifa.
M. Schaal, A. Schwartzman, and A. Angel.
Desalination, Vol 40, Nos 1/2, January 1982, p 87-94, 1 Fig, 6 Tab, 1 Ref.

Descriptors: *Desalination, Marginal costs, *Electric power costs, Electric powerplants, Costs, *Israel, Ashdod, Tel Aviv, Haifa.

The marginal kWh cost was calculated by the addition of 20 MW to the base load curve and by the division of the additional fuel consumption by the additional demand. The result was highly sensitive to the growth rate and expansion program. The marginal cost ranges between 47.4 to 60.5 mills/kWh as compared to average IEC energy cost ranging between 22.5 to 31.5 mills/kWh. The marginal cost is that which corresponds to the base load. To get the specific energy cost for the desalted water, the marginal kWh cost should be multiplied by the specific energy demand.

TRENDS IN THE APPLICATION OF SOLAR ENERGY TO WATER DESALINATION,
R. A. Brosh.
Desalination, Vol 40, Nos 1/2, January 1982, p 95-102.

Descriptors: *Desalination, *Solar energy, Distillation, Electric power costs.

Solar desalination is more expensive than fossil energy because of high capital costs for collecting systems. The types of solar energy processes are: (a) Applied to direct distillation of water, energy is collected and used in the same vessel, (b) Solar energy is collected in one unit and desalination performed in separate unit. Some calculations are made indicating development work required for successful application of solar energy.
W84-00266

SOLAR ENERGY AS A SOURCE FOR PRODUCTION OF POWER AND DESALINATED WATER,
Israel Desalination Engineering Ltd., Tel-Aviv.
A. Ophir, and N. Nadav.
Desalination, Vol 30, Nos 1/2, January 1982, p 103-124, 3 Fig, 8 Tab, 2 App, 13 Ref.

Descriptors: *Desalination, *Ponds, *Solar energy, Dual purpose plants, Dead Sea, Mediterranean.

A detailed calculation utilizing solar ponds for generation of electricity and seawater desalination are presented. Three cases are studied: single purpose electricity generation plants at the Dead Sea and Mediterranean regions and a dual purpose plant for electricity generation and seawater desalination. The results indicate that where a price of 0.6-0.7 $/ton can be economically justified, the dual purpose plant becomes the most attractive of the alternatives compared for electrical power generation as well.
W84-00267

DESALINATION PLANT USING LOW GRADE GEOTHERMAL HEAT,
Israel Desalination Engineering Ltd., Tel-Aviv.
A. Ophir.
Desalination, Vol 30, Nos 1/2, January 1982, p 125-132, 1 Fig, 1 Tab, 1 Append.

Descriptors: *Desalination, Desalination plants, Distillation, Brines, *Geothermal studies, *Israel.

Based on the possibility that a geothermal hot brine source may be found in Israel, a preliminary economic study using such a source for desalination is presented. The two cases evaluated are for a 110C and 130C brinesources. The cost of desalinated water from a geothermal brine source is 0.5 $/ton. Such a low price for seawater desalination can now be achieved only with large multi-effect distillation plants coupled with big power stations using low back pressure steam.
W84-00268

GEOTHERMAL RESOURCES IN ISRAEL,
Israel Inst. of Petroleum Engineering, Tel-Aviv.
L. Koifman.
Desalination, Vol 40, Nos 1/2, January 1982, p 133-134.

Descriptors: *Geothermal resources, Geophysics, Thermal springs, *Israel.

There are no significant geothermal anomalies in Israel. A survey of the temperatures registered on electric logs run in the oil exploration wells shows that the geothermal gradients encountered are normal, ranging from 1.7 to 2.2C/100 m in shaly formation and from about 3.0 to 4.0C/100 m in massive carbonated layers. Only in Dvora (Mount Tabor) at depths below 4000 m do we reach gradients of larger magnitudes. It was established beyond any reasonable doubt that the top Jurassic in the coastal plain, at depths of about 2700 m is at a temperature of 110C or more.
W84-00269

DESALINATION AT INLAND SITES,
Israel Desalination Engineering Ltd., Tel-Aviv.
A. Gendel.
Desalination, Vol 30, Nos 1/2, January 1982, p 135-142, 3 Fig, 3 Ref.

Descriptors: *Desalination, Desalination plants, *Dual-purpose plants, Costs, *Mediterranean-Dead Sea canal.

Locating a dual purpose desalination plant along the Mediterranean-Dead Sea Canal is feasible and should be seriously considered. The cost of water produced in the inland site will be higher by a few percentage points than in the sea side case. This cost would be considerably reduced if the product water would be mixed with locally available brackish water.
W84-00270

PRELIMINARY CONSIDERATIONS OF COMBINING A LARGE REVERSE OSMOSIS PLANT WITH THE MEDITERRANEAN-DEAD SEA PROJECT,
Mekoroth Water Co., Tel Aviv (Israel).
P. Glueckstern.
Desalination, Vol 40, Nos 1/2, January 1982, p 143-156, 3 Fig, 2 Tab, 7 Ref.

Descriptors: *Desalination, Desalination plants, *Reverse osmosis, Gravity flow, *Mediterranean-Dead Sea Canal.

The potential benefits were investigated of a reverse osmosis plant designed in conjunction with the Mediterranean-Dead Sea project in order to utilize gravity pressure as partial energy source for the desalting process. Energy requirements of alternative conceptual operating schemes were evaluated and compared to those of conventional reverse osmosis. Overall comparative economics of conventional and conjunctive systems were analyzed and discussed.

OPERATION OF A HORIZONTAL TUBE BRINE CONCENTRATOR,
Israel Desalination Engineering Ltd., Tel-Aviv.
J. Weinberg, and Y. Rotstein.
Desalination, Vol 40, Nos 1/2, January 1982, p 159-168, 2 Tab, 2 Fig, 18 Refs.

Descriptors: *Desalination, Desalination apparatus, *Scaling, Wastewater treatment, Evaporators, Concentrator.

An apparatus to concentrate solutions was developed using know how on seawater evaporators and treatment of sea and product water. A pilot plant at the Research Center in Tel-Baruch, near Tel Aviv has been operated since the middle of 1977. The plant is a single effect concentrator coupled to a condenser, with a capacity of up to 400 kg vapour per hour. The prevention of scale (Calcium sulphate, Calcium carbonate or other constituents) has been carried out by combined techniques of seeding process plus a threshold treatment.
W84-00272

ELECTRODIALYSIS UNIT: OPTIMIZATION AND CALCULATION OF ENERGY REQUIREMENT,
Ben-Gurion Univ. of the Negev, Beersheba (Israel). Div. of Membranes and Ion-Exchangers.
E. Korngold.
Desalination, Vol 40, Nos 1/2, January 1982, p 171-179, 2 Fig, 3 Tab.

Descriptors: *Desalination, Desalination plants, *Electrodialysis, Electric power demand.

An industrial unit which optimizes the parameters of the electrodialysis process has been developed. The total energy requirement with this unit is about 1.2 kWh/cu m for brackish water of 2400 ppm and 3.3 kWh/cu m for water of 5000 ppm. For sea water desalination the system may be optimized by operating it with thin cells (0.4 mm) and thin polyethylene membranes (0.1 mm). In such a system the energy requirement for the desalination of sea water will be 12 k/Wh/cu m for operation at 20C and 6.7 kWh/cu m at 70C.
W84-00273

EFFECT OF THE ENERGY CRISIS ON WATER DESALINATION AND WASTE WATER RECYCLING BY ION EXCHANGE,
Ben-Gurion Univ. of the Negev, Beersheba (Israel). Div. of Membranes and Ion-Exchangers.
Y. Egozy, and E. Korngold.
Desalination, Vol 40, Nos 1/2, January 1982, p 181-189, 3 Fig, 3 Tab, 8 Ref.

Descriptors: *Desalination, *Ion exchange, Water reuse, Wastewater renovation.

The cost, and its breakdown into components, of an ion exchange process for desalination and waste water recycling is presented. Using the effect of the 1973-4 jump in the price of energy on the cost of treatment, the expected future trend is calculated. The net energy component in ion exchange water treatment is 14.5% when lime is used for regeneration, and 17% when NaOH is used. The substitution of lime for NaOH reduces the treatment cost and makes the ion exchange process an economical method for desalination and waste water recycling. 'Non-conventional' approaches such as a continuous fixed-bed process, a system including recycling of regenerants, regeneration thermally or with waste acids are also discussed.

PRODUCTION OF ELECTRICAL POWER FROM CONCENTRATED BRINES,
Israel Desalination Engineering Ltd., Tel-Aviv.
N. Nadav, and A. Ophir.
Desalination, Vol 40, Nos 1/2, January 1982, p 197-211, 1 Fig, 2 Tab, 6 Ref.

Descriptors: Electric power, Brines, Brackish water, Falling film horizontal tube absorption condenser, Flash chamber, Condensers, Flash evaporation, Dead Sea, Israel.

Field 3—WATER SUPPLY AUGMENTATION AND CONSERVATION

Group 3A—Saline Water Conversion

The price of electrical power, produced by burning fossil energy sources has reached a level where other alternatives become competetive. One of these alternatives is dilution of concentrated brines. It is possible to regard these very concentrated brines (as well as fossil fuels) as an accumulated solar energy radiated over millions of years, causing brines to attain a very high salt concentration. Dilution of these brines results in releasing heat of dilution and the very low vapor pressure of these brines can be utilized as a driving force for vapor condensation. A source of highly concentrated brine is available at the Dead Sea Works where 88 million tons of such brine is today returned to the Dead Sea as waste streams. Dilution of this brine at a ratio of three (brine) to one (vapor) by weight can supply 40 MW of electrical power. The proposed process is based on the use of two well-proven process elements, a falling film horizontal tube absorption condenser and a flash chamber.

THE JOINT U.S.-ISRAEL DESALINATION PROJECT STATUS REPORT AND THE IMPACT OF RISING ENERGY COSTS ON THE PROGRAM,
Israel-U.S. Desalination Project Authority, Tel-Aviv.
A. Peled, and J. Finke.
Desalination, Vol 40, Nos 1/2, January 1982, p 217-223, 9 Figs.

Descriptors: *Desalination, Desalination plants, *Multieffect distillation, Seawater, *Distillation.

The Joint U.S.-Israel Desalination Project is discussed which was initiated in 1975 with the main objective of developing, designing, constructing and demonstrating the operation of a large -5/10 MGD - MED seawater desalination plant, using exhaust heat from an existing 50-MW steam power plant.
W84-00276

THE IMPACT OF DESALINATED WATER QUALITY ON ENERGY COSTS,
Italconsult, Rome (Italy).
E. Gabrielli.
Desalination, Vol 40, No 3, p 391-394, March 1982. (Comprising the Round Table Conference on Influence on Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980). 4 Ref.

Descriptors: *Desalination, Seawater, *Energy, *Costs.

Lack of clarity in defining the scope of work of a desalination process may often lead to questionable or meaningless results when economic analysis is performed. In particular the incidence of the energy cost cannot be compared when different plants treat the same raw material, in this case seawater, but yield different products; that is to say waters which have residual TDS differing by orders of magnitude and which are not therefore necessarily equivalent for the application in question. Criteria are suggested for ensuring clearer definition of the problem in order to help evolve a methodology which allows processes to be compared on a perfectly sound economic basis.

DEVELOPMENT OF DISTILLATION PROCESSES RESPONSIVE TO ENERGY COST ESCALATIONS,
California Univ., Berkeley. Sea Water Conversion Lab.
H. H. Sephton.
Desalination, Vol 40, Nos 3, p 375-384, March 1982. (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), 5 Fig, 20 Ref.

Descriptors: *Desalination, Desalination plants, *Desalination apparatus, *Distillation, Energy, Costs.

Recent developments in distillation processes that respond to the continuing escalation in energy cost are reviewed. The most effective developements are considered to be those providing increased performance ratios and heat transfer rates, the utilization of waste heat or low grade heat including insolation, and improvements in the reliability of equipment and processes within reasonable capital cost levels. Suggestions are offered as themes for future research and development in each of these area.
W84-00278

ENERGETIC ASPECTS OF THE FOULING OF MSF DESALINATION PLANTS WITH AND WITHOUT THE USE OF ON LOAD BALL CLEANING SYSTEM,
K. Eimer.
Desalination, Vol 40, No 3, p 363-372, March 1982. (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), 1 Tab, 8 Fig, 18 Ref.

Descriptors: *Desalination, Desalination plants, *Multistage flash, Energy, Fouling, Load ball cleaning system, Scaling.

Multi stage flash (MSF) desalination plants are designed with specific permissible fouling factors. When these conditions are met, the performance is said to 'meet design'. With single-purpose desalinators, fouling of the brine heater can be compensated for by increasing the steam pressure without substantial increase of heat consumption and within the limits of the boiler pressure. With dual-purpose desalinators, the brine heater pressure will influence the efficiency of the turbine process. Fouling of the heat recovery section increases the heat consumption of the MSF process. The distillate production can be maintained within the limits of the boiler. Typical 'design fouling factors' have been compiled from literature. The influence of fouling factor on specific heat consumption has been calculated for typical MSF design conceptions, as well as the increase of water costs per cu m with different fuel prices. The costs of various scale prevention methods have been evaluated. The effectiveness of such countermeasures can be quantified by plant experience. This analysis of cost/return gives a basis for a correct economic comparison.
W84-00279

SEAWATER REVERSE OSMOSIS WITH ENERGY RECOVERY,
Esmil International B.V., Amsterdam (Netherlands).
W. A. G. Hoeting.
Desalination, Vol 40, No 3, p 357-361, March 1982. (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), 2 Tab, 1 Fig.

Descriptors: Desalination, Desalination plants, Reverse osmosis, Seawater, Energy recovery, Porto Sauto, Madeira Islands.

The Porto Santo seawater reverse osmosis plant has been designed to provide per day 500 cu m of potable water with a total dissolved solids content of 500 ppm from seawater with a total dissolved solids content of about 34000 ppm. The plant consists of four independent units with an output of 125 cu m per day each. Three units are fed by high pressure pumps equipped with electro-motors and one unit by a high pressure pump equipped with a hydro-turbine. The high pressure reject stream from each unit is directed into a manifold pipe which powers the hydroturbine. In this way power consumption of the high pressure pump is reduced by 25%. Without energy recovery consumption would have been 7.5 kWh/cu m and with the installed turbine this is as low as 5.6 kWh/cu m of product.

HIGH TEMPERATURE DISTILLATION PROCESS WITH SEA WATER FEED DECALCIFICATION PRETREATMENT,
Aquila Univ. (Italy). Ist. di Chimica Applicata ed Industriale.
D. Barba, G. di Giacomo, F. Evangelista, and G. Tagliaferri.
In: Desalination, Vol 40, No 3, p 347-355, March 1982. (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Producion during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), 1 Tab, 6 Fig, 13 Ref.

Descriptors: *Desalination, Desalination plants, Distillation, Ion exchange, Seawater, *Pretreatment of water, *Cation exchange.

The performance ratio of a desalination plant can be increased to reach 16-18 by coupling it with a decalcification pretreatment by ion exchange of the sea-water make-up, thus making MSF comparable with RO from an energy point of view. A new strong cationic resin DECAL has been tailored; its main features are high selectivity towards the calcium ion and low concentration of the regenerating brine. These characteristics make it compatible with the normal operating range of multiflash plants and very suitable for the above service, when compared with other resins. The optimum coupling conditions of the whole plant, lie between 140 and 150C for the top brine temperature and 2 to 2.5 for the brine concentration factor. In these conditions it is possible to operate with a sea-water resin bed ratio higher than 20.
W84-00281

INVESTMENT COSTS AND ENERGY CONSUMPTION OF THE MSF/FBE IN COMPARISON WITH THE MSF,
Esmil International B.V., Amsterdam (Netherlands).
J. P. P. Tholen.
Desalination, Vol 40, No 3, p 341-345, March 1982. (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, Septebmer 1980), 3 Tab, 3 Fig.

Descriptors: *Desalination, Desalination plants, *Distillation, *Multistage flash, Fluidized bed heat exchanger, Costs, Energy loss.

The use of the MSF process in seawater desalination is broad because of simplicity and reliability and an improvement of this process has been proven in the use of the fluidized bed heat exchanger. The choice of most economical gain ratio of a multistage flash evaporator is very dependent on energy cost, i.e. steam- and electricity cost. Because of lower investment and electricity costs the MSF/FBE has always lower product water cost than the MSF with equal gain ratio.
W84-00282

TRENDS IN THE MAJOR COST COMPONENTS OF MSF DESALTING AND THEIR IMPLICATIONS FOR FUTURE THERMAL DESALTING PLANT,
Binnie and Partners, London (England).
F. C. Wood.
In: Desalination, Vol 40, No 3, p 327-337, March 1982 (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), 4 Tab, 3 Fig, 7 Ref.

Descriptors: *Desalination, Desalination plants, *Distillation, Multistage flash, *Posts, Reverse osmosis.

The capital and operating costs of multistage flash (MSF) seawater desalters have increased drastically over the past decade. Analysis of trends in their major construction and operational costs permits conclusions to be drawn concerning the direction of future developments. If present trends continue, arid, oil-producing countries will require plants of low initial cost, high reliability and ease of operation, rather than new and advanced desalting concepts. On the other hand, oil-importing countries needing desalting must develop less fuel-intensive processes. Although seawater reverse osmosis can meet these needs, a market for dual-purpose plant of high Performance Ratio will persist, particularly where flexibility of operation is required. Hybrid desalters, combining power-using and thermal desalting techniques, will be developed in these countries. Mechanical vapour compression combined with multiple-effect evaporation and MSF feed preheating is one such process.
W84-00283

SEAWATER DESALTING ENERGY REQUIREMENTS AS A FUNCTION OF VARIOUS LOCAL CONDITIONS,
Burns and Roe, Inc., Oradell, NJ.
A. C. F. Ammerlaan.
In: Desalination, Vol 40, No 3, March 1982 (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), p 317-326, 10 Figs.

Descriptors: Desalination, Desalination plants, Vapor compression, Multistage flash, Reverse osmosis, Energy efficiency.

Energy consumption has been of prime concern to the equipment designer. With today's energy costs accelerating at an unprecedented rate, energy efficiency of desalting equipment is getting even more attention. However, local conditions have a considerable effect upon the ultimate selection and design of almost every desalting plant. Once these have been taken into account, by establishing the economic optimum and desired safeguards for the specific local conditions, energy efficiency of the desalting equipment usually is considerably less than the maximum that conceivably could be achieved. One finds that the inventors' and designers' efforts to reduce energy requirements certainly have not been in vain but, on the other hand, can be severely diluted by compromises necessitated by local conditions. Some of these conditions are explored along with their effects upon the energy efficiency of seawater desalting plants for the desalting processes: vapor compression, multistage flash, and reverse osmosis.
W84-00284

COST OF PRODUCING POWER AND WATER IN A COMBINED POWER STATION AND SEAWATER DESALINATION PLANT,
Abu Dhabi National Oil Co. (United Arbab Emirates).
R. Al-Assar, H. E. Homig, and K. Maurath.
In: Desalination, Vol 40, No 3, March 1982 (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), p 311-316, 2 Figs, 1 Tab.

Descriptors: *Desalination, Desalination plants, *Dual purpose plants, Powerplants, Seawater desalination, Electric power costs, *Costs.

The Ruwais Utilities complex is taken as an example to show how the relationship between power and water costs for a dual-purpose plant can be represented in a nomogram. The preparation of such a nomogram for a specific case is simple in principle, but calls for a considerable amount of computing because the cost calculations have to be performed for a large number of variants. This task is greatly facilitated by using suitable EDP programs.
W84-00285

AN EVALUATION OF THE ENERGY REQUIREMENTS OF DESALINATION PROCESSES ON THE BASIS OF THE FUEL-USE PERFORMANCE RATIO,
I. Kamal, and G. F. Tusel.
In: Desalination, Vol 40, No 3, March 1982 (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), p 283-295, 5 Figs, 6 Refs.

Descriptors: *Desalination, Desalination plants, *Reverse osmosis, *Distillation, *Multistage flash, *Multiple effect boiling, *Vertical tube foam evaporation, Single purpose, Dual purpose, Energy requirements, Fuel use performance ratio.

The fuel-use performance ratio is defined as the quantity of water produced, in kg, per 1000 kJ of the heat content of the fuel used for supplying thermal, mechanical and/or electrical energy to the desalination plant. The concept is used to evaluate the energy requirements of the major seawater conversion processes - RO, MSF, multiple effect boiling (as exemplified in the vertical tube foam evaporation process), vapor compression and hybrids of the thermal processes - for three types of plants: (a) single-purpose (water only), (b) dual-purpose (power/water) involving 'power loss' and (c) dual-purpose (power/water) utilizing waste heat. Only distillation systems based on waste heat can compete with the low energy requirements of reverse osmosis.
W84-00286

ENERGY ADVANTAGES OF REVERSE OSMOSIS IN SEAWATER DESALINATION,
Du Pont de Nemours (E.I.) and Co., Wilmington, DE.
C. T. Sackinger.
In: Desalination, Vol 40, No 3, March 1982 (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), p 271-281, 8 Figs, 4 Refs.

Descriptors: *Desalination, Desalination plants, *Reverse osmosis, Seawater desalination, Energy, Electric power costs, *Costs.

The very rapid increase in energy costs during the past three years is causing a change in the preferred process technology for seawater desalination. The phase changes, evaporation and condensation, required in the distillation processes make them more energy intensive than the ambient temperature liquid separation that occurs in the reverse osmosis (RO) process. The RO process and how to calculate its energy consumption are described. The RO process requires only 5-7 kWh/cu m of product water compared to 15-16 kWh/cu m required by the most efficient distillation process. The productivity of a large dual purpose electricity/RO water plant is compared to the productivity of a commercially purchased state-of-the-art dual purpose electric/distillation water plant that is currently under construction. The RO potable water productivity is about twice the distillate flow at the same fuel rate.
W84-00287

CONSIDERATIONS OF ENERGY CONSUMPTION IN DESALINATION BY REVERSE OSMOSIS,
UOP, Inc., San Diego, CA. Fluid Systems Div.
A. B. Riedinger, and C. E. Hickman.
In: Desalination, Vol 40, No 3, March 1982 (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), p 259-270, 10 Fig.

Descriptors: *Desalination, Energy consumption, *Reverse osmosis, Feedwater treatment, Osmotic pressure.

The primary factors affecting the energy consumption of a reverse osmosis (RO) plant are considered. These are the osmotic pressure of the feedwater, the feedwater temperature, the water recovery, and the relationship between the water flux and salt flux characteristics of the membrane. In addition, the required permeate quality may have several indirect effects on the energy consumption. Permeate quality standards may impose minimum operating pressures, limit the recovery, and/or require treatment with a full or partial 2nd. stage. As a general rule, the energy required increases with increasing feed salinity and increasing permeate quality. For any given recovery, a single stage system will require less energy than a partial two stage system. However, for a specified permeate quality, a partial two stage system can operate at a higher overall recovery and a lower energy consumption than a single stage system. Energy recovery systems can recover between 50 and 90% of the available energy consumption. Studies have shown that with an energy recovery system, the minimum energy consumption occurs at a first stage recovery of 30 to 35%. Currently, very few energy recovery systems are in use because of their high capital cost, but as energy recovery systems become more available and reliable, they will greatly increase the energy efficiency of RO plants.

DISTILLATION AND REVERSE OSMOSIS ENERGY CONSUMPTION AND COSTS,
Preece, Cardew and Rider, Brighton (England).
N. M. Wade, and M. R. Hornsby.
In: Desalination, Vol 40, No 3, March 1982 (Comprising the Round Table Conference on the Influence of Thermodynamic and Economic Aspects in Energy Consumption for Water Production during the 7th International Symposium on Fresh Water from the Sea, Amsterdam, September 1980), p 245-257, 2 Tab, 4 Figs.

Descriptors: *Desalination, Desalination plants, Distillation, Reverse osmosis, Energy, Costs, *Electric power demand.

Energy requirements are compared of single and dual purpose multistage flash distillation with a seawater reverse osmosis (RO) plant. Energy consumptions are given both as heat and power consumptions for distillation and as power consumption for RO. To enable a true comparison to be made these inputs are referred back to the heat inputs from fuel needed at the boiler plant or appropriate thermal power plant. Energy recovery is also considered for reverse osmosis and it is shown that the energy input can be expected to decrease by some 35% for a typical example. Although the prime energy input needed for reverse osmosis is shown to be substantially lower than for dual purpose distillation, the overall costs taking account of capital charges, energy, replacements and other operating costs, are found to be in a band width of about 5% for plants in the range of 5000 to 15000 cu m/day. Reverse osmosis plant water costs are significantly less than distillation if membrane life increases from 3 years to 5 years, particularly with small plant capacities.

3B. Water Yield Improvement

GEOPHYISCAL EXPLORATION SURVEYS FOR GROUND WATER IN THE SAN PEDRO BASIN, ARIZONA,
Arizona Univ., Tucson. Coll. of Earth Sciences.
J. S. Sumner, and P. F. Halvorson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110808, Price codes: A03 in paper copy, A01 in microfiche. Water Resources Research Center Completion Report, August 1983. 24 p, 2 Fig, 2 Tab, 40 Ref. OWRT A-108-ARIZ(1), 14-34-0001-1103.

Descriptors: Geology, *Gravity studies, Subsurface investigations, Model studies, *Arizona, *Geophysical exploration, *Groundwater, San Pedro basin.

To increase knowledge of the subsurface geology in the San Pedro Valley, Southeastern Arizona, several hundred additional gravity measurements were taken in the region. The new gravity values were supplemented by private data donated to this project and to the Arizona Gravity Data Base. The primary purpose of the gravity research was to obtain more information about the thickness and extent of the water-bearing alluvium in the San Pedro Basin. Two-dimensional cross-sectional models of the best gravity profiles were generated. Geologic information, especially in the way of formation density values, was added to the gravity models whenever possible. The gravity station density of the southern part of the study area (upper San Pedro Basin) was such that a three-dimensional subsurface model can be developed. Well data and a general knowledge of the geology in the San Pedro Valley were used to help constraint the variables involved in modeling the gravity data. It appears that a considerable resource of ground water exists in the San Pedro Basin in the area of this study. Approximately 50 x 10 super 6 acre-feet underlie the northern portion between Winkieman and Benson and 100 x 10 super 6 acre-feet south of Benson for a total of 150 x 10 super 6 acre feet. The gravity method has proven to be successful in outlining the concealed bedrock edges of the basin, made obscure by weathering and a soil veneer.

3C. Use Of Water Of Impaired Quality

OPTIMIZATION OF PRIMARY PRODUCTION BY THE HALOPHYTIC ALGA, DUNALIELLA SALINA, IN SALINE WATER,
New Mexico Water Resources Research Inst., Las Cruces.
R. Roubicek, and L. White-Hosford.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113604, Price Codes: A04 in paper copy, A01 in microfiche. Technical Report No 166, April 1983. 53 p, 13 Fig, 10 Tab, 34 Ref. OWRT A-067-NMEX(1), 14-34-0001-2133.

Descriptors: *Algal growth, *Halophyte, Growth rate, *Biomass, *Production, Brackish water, Saline water, Respiration, Osmoregulation, Photosynthesis, *Dunaliella, *Metabolism, Algae.

The industrial cultivation of algal biomass is a very attractive project for both primary and secondary metabolite production. Solar energy conversion via algal cultivation results in yields which can be more than 100 times greater per acre than terrestrial crops. However, algal biomass production has not yet been shown to be economically feasible due to traditional technologies in which algae are grown in large shallow ponds. Because of the low depth of the ponds, an extremely large area is required to build a minimally economical production unit. Many other factors render this process difficult to control. An abundance of saline underground water can be found in arid or semi-arid areas with solar availability. The use of shallow ponds for algal biomass production in these areas enhances the evaporation rate of the water making salinity a limiting factor. For these reasons, the behavior of halophytic algae of the genus Dunaliella and the feasibility of employing submerged cultivation in a photo-bioreactor using brackish and saline media was investigated. Dunaliella salina produces large quantities of glycerol as a osmoregulative response to high concentrations of salts. Dunaliella bardawil, under the same condition produces high concentrations of B-carotene. In the first stage of experimentation the most productive isolates were selected and conditions of maintenance were established. The selected isolates were tested for growth in laboratory shaker experiments and finally laboratory pilot plant experiments were carried out in a 14 liter submerged culture.

ASSESSING BRACKISH WATER FOR GUAYULE RUBBER PRODUCTION,
Arizona State Univ., Tempe. Div. of Agriculture.
T. L. Righetti, and R. A. Backhaus.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113612, Price codes: A02 in paper copy, A01 in microfiche. Water Resources Research Center Completion Report, Univ. of Arizona, Tucson, September 1983. 18 p, 7 Fig, 2 Tab, 13 Ref. OWWR A-116-ARIZ(1), 14-34-0001-2103.

Descriptors: *Guayule, Hydroponics, Parthenium argentatum G., Plant greeding, Plant selection, Salinity solution culture, Water quality, *Brackish water, Rubber production, *Arizona, Tempe, *Plant tolerance.

A screening procedure for salt tolerance in guayule has been developed. Two small scale and one large-scale (100 liter tanks) solution culture screening trials have been completed. Producing 1,200 to 2,000 uniform transplants from germplasm varying in germination time and percentage is cumbersome, but the following procedure has been developed for routine use. Seeds are pregerminated in aerated distilled water then sprouted in flats of peat-vermiculite under an automated mist system. After three weeks seedlings are transplanted into individual containers and grown another three weeks before transplanting into solution culture tanks. Aeration is provided with a Gardner-Denver rotary blower. Salt stresses are gradually implemented over a two-week period. Plants are harvested after ten weeks. A portion of the experiment is not included in the destructive harvest so some seedlings showing striking salt resistance or sensitivity can be maintained for further study. Within strain variability makes it difficult to statistically detect differences among strains. It may be more useful to select tolerant individuals for inclusion in breeding programs than to identify resistant strains. Even with the variability encountered some strain difference are apparent. Guayule strain N396 has shown superior survival when stressed with magnesium chloride and appears to tolerate sodium chloride stress better than other strains. Differences are not due to differing uptake of Ca, K, Mg, or Na.

HUGE SEAWATER PLANT PERFORMS AS PLANNED,
S. L. Matheny.
Oil and Gas Journal, Vol 78, No 27, p 87-88, 92, July, 1980. 3 Fig.

Descriptors: *Seawater, *Desalination plants, Demineralization, Desalination apparatus, Water supply development, Industrial water, Water quality, Water treatment, *Saudi Arabia.

A seawater treatment plant designed to take in a volume of 19 million barrels per day is described. The treated water is employed in injection wells in the Ghawar oilfield, Saudi Arabia. The plant cost about $500 million to construct. The plant went onstream in June 1978. The intake side of the plant is sealed off by a rock wall basin. The seawater first passes through a bar screen which separates out solids larger than 1 inch in diameter. The drum screen, next in line, filters out all particles over 2 mm in diameter. One hundred lb/hr of hypochlorite solution is injected into the stream before it goes into the canal at a chlorine content of about 4 ppm. Supplemental chlorine is added as needed. The chlorinated water passes through four horizontal Baker sand filters. Each deaerator can handle 500,000 b/day at 1 atmosphere pressure. Each deaerating column has 16 trays. The system is designed to deliver injection water of a quality which will not plug the injection wells. (Baker-FRC)

INDUSTRIAL WATER REUSE VERSUS NET WATER LOSS,
Delaware River Basin Commission, Trenton, NJ.
S. D. Selzer, and P. J. Webber.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111822, Price codes: A05 in paper copy, A01 in microfiche. Completion Report OWR/RU-83/2, U.S. Dept. of the Interior, Bur. Reclamation, Washington, DC, June 1983. 84 p, 4 Fig, 7 Tab, 12 Ref, 2 Append. OWRT C-00079-R(No 0493)(1).

Descriptors: *Water loss, *Consumptive use, *Water reuse, *Industrial water, *Cooling water, Cooling towers, *Delaware River, Evaporation, Heat exchangers, *Dry cooling, *Heat recovery, *Reuse factor, Petroleum industry, Chemical industry, Paper industry, Food industry, Primary metal industry.

Water use and other data of 13 Delaware River Basin industrial plants were examined to determine the impact of increased reuse of water upon consumptive use of water. The plants were of the petroleum, chemical, paper, food, and primary metal industries. The change over time, year 1971 to 1981, of the reuse factor (reuse/withdrawal) was compared to change in consumptive use per unit of product. The reuse factor was increased for 9 plants. The consumptive use per unit of product was decreased for 7, increased for 1, and remained constant for 1 of these plants. The reuse factor was not measurably changed for 4 plants. The consumptive use per unit of product was decreased for 2 and was increased for 2 of the 4 plants. For 86 plants in the Basin, including the 13 discussed above, the combined consumptive use was decreased from 1971 to 1981. Although there were limited quantitative data, none of the 86 appeared to have experienced a decrease in the reuse factor over the 1971-81 decade. Causes for increased reuse have included minimization of water and waste treatment and energy costs. Causes for decreased consumptive use have included increases in dry cooling and heat recovery.

THE EFFECT OF MOISTURE STRESS ON CORN PRODUCTION IN THE HIGH PLAINS,
New Mexico State Univ., Las Cruces. Dept. of Agricultural Engineering.
T. W. Sammis, and D. Smeal.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113653, Price codes: A04 in paper copy, A01 in microfiche. New Mexico Water Resources Research Institute Technical Report No 171, Las Cruces, June 1983.

73 p, 10 Fig, 26 Tab, 3 Ref, 4 Append. OWRT B-069-NMEX(1), 14-34-0001-0234.

Descriptors: *Corn, *Crop production, Computer model, *Moisture stress, Irrigation, High plains, Crop yield, Evapotranspiration, Simulation, Model studies, Soil moisture.

Evapotranspiration and yield were measured for selected deficit irrigation and nitrogen levels, and the data used to derive the water production function. Nitrogen stress limited yield but did not affect the water production function relationship. However, the water production functions did vary in their intercept between years. These differences may have been due to differences in yearly soil evaporation. The slope of the water production functions of the water use efficiency was the same over years. Corn growth was modeled using a physiologically based model. The model simulated biomass and grain yield under non-moisture stress conditions within 10% of the measured values, and over estimated production as moisture stress increased. Modifications to the model to include the effect of moisture stress on leaf size and the effect of hail damage on corn growth increased the model's predictability, but still the model over estimates corn growth under soil moisture stress conditions. The model did not do a satisfactory job of predicting corn growth when competition between plants was decreased due to the low planting density that occurred in 1982.

SOIL CRUSTING AFFECTS WATER CONSERVATION AND INFILTRATION,
Kansas Water Resources Research Inst., Manhattan.
D. M. Powell, and J. M. Steichen.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113695, Price codes: A02 in paper copy, A01 in microfiche. Contribution No 232, March 1983. 24 p, 7 Fig, 8 Tab, 13 Ref, 1 Append. OWRT A-108-KAN(1), 14-34-0001-2118.

Descriptors: *Rainfall infiltration, *Infiltration rate, *Mathematical models, *Surface sealing, Tillage, *Crop residue, *Soil crusting, *Kansas, Model studies, *Water conservation.

An infiltration model is developed to include formation of a soil crust under transient conditions. A Soil-Crust Index has been defined and experimentally tested for two Kansas soils. The infiltration model utilizing the Soil-Crust Index was field tested on several tillage practices but for only one soil. The results of the laboratory experiments failed to indicate that the Soil-Crust Index can be applied across soil textures. Additional information is needed, particularly as pertains to high Soil-Crust Index values, before this can be adequately determined. The field experiments indicated that simulated infiltration trials may adequately predict infiltration for different tillage practices provided surface-depression storage can be properly estimated.

CAREFUL CROP PLANNING CUTS STRAIN ON IRRIGATION WATER SUPPLY.
New Zealand Journal of Agriculture, Vol 145, No 6, p 15-16, December, 1982.

Descriptors: *Irrigation efficiency, *Scheduling, Agronomy, Water conservation, *Water demand, Planning, Conservation, *New Zealand.

Careful crop planning can help match irrigation needs with scarce supplies during a drought such as was experienced recently in New Zealand. This is done by selecting crop types with regard to their watering demand pattern and by timing sowing dates so that peak water demands for different areas do not coincide. If a crop plan shows an overextension of water supplies, altering the proportions of crops and/or changing sowing dates can even the water demand. An example illustrates that barley, spring peas, and white clover all need irrigation in early December. Replacing some of these crops with autumn peas (irrigated in mid to late November), linseed (irrigated mid-October), or autumn wheat (irrigated early November) would overcome this problem. Altering sowing dates has little impact in autumn, but in spring a 1 month delay in sowing can postpone the critical growth stage about 1-3 weeks. During hot dry weather the water demand schedule is condensed. (Cassar-FRC)

TRICKLE IRRIGATION VS. NO-IRRIGATION OF FIVE HORTICULTURAL CROPS IN PENNSYLVANIA,
Agricultural Research Service, Shafter, CA. Cotton Research Station.
W. R. DeTar, D. F. Kibler, D. W. Grenoble, R. Daniels, and R. H. Cole.
Transactions of the ASAE, Vol 26, No 1, p 82-86, 1983. 1 Tab, 10 Ref.

Descriptors: *Trickle irrigation, *Crop yield, Irrigation programs, Potatoes, Strawberries, Irrigation, Water supply, Water conservation, Raspberries, Apples, Cantaloupes, *Pennsylvania.

Several irrigation experiments were set up in 1979, 1980, and 1981 on five crops, strawberries, raspberries, potatoes, apples, and cantaloupes, with irrigated vs. non-irrigated treatments being the main point of interest. The trickle irrigation system was found to be a very useful tool for this type of field study in that it provided excellent moisture control and permitted proper randomization and replication within relatively small land areas. Significant yield differences were found only in the 1980 potatoes and the 1980 cantaloupes. In 1980, non-irrigated Norchip potatoes yielded 35% less than irrigated potatoes. A drought in June of 1980 caused the non-irrigated cantaloupes to produce 15.5% less than the irrigated treatment. However, a drought in August of 1981 caused no significant reduction in cantaloupe yield, leading one to conclude that irrigation of cantaloupes is not needed during the 3 weeks just before harvesting. The use of single chambered perforated tubes in every other potato row did not reduce yields, in spite of an obvious lack of uniformity of water application. (Baker-FRC)

ESTIMATING LOSSES FROM A ROTATING-BOOM SPRINKLER,
Agricultural Research Service, Morris, MN. North Central Soil Conservation Research Center.
A. S. Dylla, and H. Shull.
Transactions of the ASAE, Vol 26, No 1, p 123-125, 1983. 1 Fig, 1 Tab, 13 Ref.

Descriptors: *Sprinkler irrigation, *Evaporation, Water loss, Irrigation practices, Irrigation, Wind drift, Wind, Mathematical equations, Estimating equations.

Evaporation and wind drift losses from a moderate sized sprinkler system operated in Minnesota were investigated to provide better information for designing and managing irrigation systems in a windy, humid and temperate climate. Spray evaporation and wind drift losses were determined from the operating system by measuring differences between the water pumped through the system and the water reaching vegetative and soil surfaces in the sprinkler pattern area. A grid array of sprinkler water collectors was used. Water loss amounts and climatic data for 31 sprinkler runs were used to calculate a multiple linear regression loss estimating equation. It was concluded that the difference between the metered volume of water pumped through an irrigation system and that reaching soil and crop surface, as calculated from grid-arrayed collector cans, was a reasonable estimate of the combined spray evaporation and wind drift losses. Although such losses are related to the evaporative conditions of the atmosphere during sprinkling, it is not prudent to fail to recognize that the losses are also related to the peculiar water discharge. For calculating the percent combined evaporation and wind drift losses from a large rotating-boom sprinkler system operating in a semi-humid temperate climate, the equation given is sufficiently accurate for irrigation planning and scheduling and determining gross water requirements. (Baker-FRC)

ENERGY AND WATER REQUIREMENTS FOR SUBIRRIGATION VS. SPRINKLER IRRIGATION,
Earlham School of Religion, Richmond, IN.
F. C. Massey, R. W. Skaggs, and R. E. Sneed.
Transactions of the ASAE, Vol 26, No 1, p 126-133, 1983. 7 Fig, 9 Tab, 22 Ref.

Descriptors: *Subsurface irrigation, *Sprinkler irrigation, *Energy, Model studies, Irrigation programs, Irrigation practices, Seepage, Water loss, *North Carolina.

Water and energy requirements of subirrigation and sprinkler irrigation systems for three sites in eastern North Carolina were determined. The specific objectives of the study were to obtain soil input data and design both subirrigation and sprinkler irrigations; to simulate the operation of the irrigation systems over several years of climatological record to evaluate the performance of each system; and to evaluate the amount of water and energy required, on the average, for comparable sprinkler irrigation and subirrigation systems in humid regions. It was concluded that subirrigation required more water than sprinkler irrigation for the cases considered. Sprinkler irrigation required 4 to 8 cm less water on the average than the subirrigation when seepage losses and efficiencies were taken into account. When a surface water supply was assumed, subirrigation required only about 9 and 6% of the energy required for the 340 and 690 kPa sprinkler irrigation systems, respectively. When a deep water supply was used, subirrigation offered a 20% savings in the amount of energy required for the 340 lPa system under sandy loam soil conditions. The climatic conditions had an effect on the volume of water pumped and therefore on the total energy requirements. Differences in energy requirements for the subirrigation and sprinkler irrigation systems at Jacksonville, Florida and Indianapolis, Indiana, were about the same as given in the study for North Carolina conditions. (Baker-FRC)
W84-00183

IRRIGATION UNIFORMITY EFFECT ON LAND AND WATER ALLOCATION,
Technion - Israel Inst. of Tech., Haifa. Dept. of Agricultural Engineering.
I. Seginer.
Transactions of the ASAE, Vol 26, No 1, p 116-122, 1983. 6 Fig, 6 Ref.

Descriptors: *Irrigation, *Water supply, Water conservation, Crop yield, *Water distribution, Mathematical studies, Mathematical equations, Water allocation.

The problem of allocating land and water to a single irrigated crop is treated, with emphasis on the effect that water distribution uniformity should have on the decisions to be taken. Eventually considerations of uniformity should be incorporated in more complex allocation problems. Analytical solutions are developed for simple production and distribution functions. Three general situations become apparent: (a) limiting water, when all water should be used for irrigation; (b) limiting land, when all available land should be irrigated; and (c) limiting crop, when it is not justified to irrigate the given crop. For any given production function, the optimal seasonal water application may vary widely, depending on the price system, the availability of land and water, and the uniformity of water application. The returns for improving the uniformity coefficient are affected strongly by the curvature of the production function, but only slightly by the relative availability of land and water. (Baker-FRC)
W84-00184

DRIP IRRIGATION APPLICATION EFFICIENCY AND SCHEDULES,
Hawaii Univ., Honolulu. Dept. of Agricultural Engineering.
I. P. Wu, and H. M. Gitlin.

Transactions of the ASAE, Vol 26, No 1, p 92-99, 1983. 9 Fig, 1 Tab, 10 Ref.

Descriptors: *Irrigation practices, *Application rates, Hydraulics, Irrigation, *Drip irrigation, Efficiency, Irrigation programs.

A drip irrigation system has a potential for a higher application efficiency than the other irrigation systems such as furrow and sprinkler. Drip irrigation application efficiency can be estimated for all types of emitter flow profiles caused by hydraulic design. A relationship was determined between drip irrigation application efficiency and percent of deficit for design criteria for 10% and 20% emitter flow variation. Drip irrigation application efficiency can be estimated for emitter flow variations stemming from both hydraulics and manufacturing. The irrigation time can be calculated based on the total water requirement, the allowable deficit, the actual total discharge, and the irrigation application efficiency. The emitter flow variation in a drip irrigation design or any nonuniformity of emitter flow will result in an extra amount of irrigation to meet the water requirement for the whole field. If any percent of deficit is allowed, the extra amount of irrigation will be reduced. A water saving of 10-30% can be made by allowing a 3-6% deficit in the irrigation scheduling. The allowable deficit, however, depends on the crop tolerance to soil moisture deficiency. The assumption that the total emitter flow variation is a normal distribution has not been verified using laboratory data or field measurements. However, the contribution of hydraulics to the total variation is only a small portion, while a larger portion is contributed by manufacturing variation which is normally distributed. Deficit irrigation increases water application efficiency and can achieve an application efficiency of 100%. (Baker-FRC)
W84-00192

DESIGN PROCEDURE OF SPRINKLING LATERALS: THE MATHEMATICAL BACKGROUND OF A COMPUTERIZED AID: COMMENTS,
Ben-Gurion Univ. of the Negev, Sde Boker (Israel). Jacob Blaustein Inst. for Desert Research.
G. Oron.
Agricultural Water Management, Vol 5, No 4, p 375-377, December, 1982. 3 Ref.

Descriptors: *Design criteria, *Mathematical equations, *Sprinklers, Sprinkler irrigation, Sprinkling, Computers, Irrigation.

Methodology used in the procedure for sprinkling lateral design by Pleban and Amir in the above titled paper, published in Agriculture Water Management, Vol 3, p 269-278, 1981, is praised, but comments are presented on the equation used to describe the flow rate. The original authors express the flow rate through the sprinkler by a polynomial third degree, and had used a polynomial expression for the discharge-pressure head function of emitters. The current author would have preferred the use of an exponential expression. It was out of practical considerations only that the original authors decided against the use of an exponential expression and used instead the polynomial one. It is noted that without changing the design procedure either expression could be used where it is practically justified. (Baker-FRC)

4A. Control Of Water On The Surface

OPTIMAL OPERATION OF A MULTIPLE RESERVOIR SYSTEM,
California Univ., Davis. Dept. of Land, Air and Water Resources.
M. A. Marino, and H. A. Loaiciga.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111665, Price codes: A14 in paper copy, A01 in microfiche. California Water Resources Center Completion Report, University of California, Davis, September 1983. 298 p, 27 Fig, 75 Tab, 86 Ref. OWRT-A-088-CAL(2).

Descriptors: *Reservoir operation, *Optimization, *Model studies, Energy, Streamflow, Multiobjective planning, *California, Central Valley Project, *Multiple reservoir systems.

A methodology to obtain optimal reservoir operation policies for a large-scale reservoir system is presented. The model maximizes the system annual energy generation while satisfying constraints imposed on the operation of the reservoir network. The model incorporates the stochasticity of river flows and keeps future operating schedules up-to-date with the actual realization of those random variables. It yields medium-term (one-year ahead) optimal release policies that allow the planning of activities within the current water year, with the possibility of updating preplanned activities to account for uncertain events that affect the state of the system. The solution approach is a sequential dynamic decomposition algorithm that keeps computational requirements and dimensionality problems at low levels. The model is applied to a nine-reservoir portion of the California Central Valley Project and the results are compared with those from conventional operation methods currently in use, showing that the use of the model can improve the levels of energy production (about 30% increase) while the optimal release policies meet satisfactorily all other functions of the reservoir system. Sensitivity analysis is conducted to assess the optimality of the solutions and several alternative formulations of the model are developed and tested, the results showing the robustness of the optimal policies to the choice of model. (Snyder-California)

PREDICTING DAILY IRRIGATION PROJECT DIVERSIONS,
Idaho Univ., Moscow. Dept. of Agricultural Engineering.
S. Kim, J. R. Busch, and K. H. Yoo.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111855, Price codes: A05 in paper copy, A01 in microfiche. Idaho Water and Energy Resources Research Institute Completion Report, Moscow, October 1983. 72 p, 13 Fig, 3 Tab, 20 Ref, 3 Append. OWRT A-074-IDA(1), 14-34-0001-2114.

Descriptors: Irrigation systems, *Irrigation districts, Water management, *Irrigation practices, Water demand, *Diversions, Prediction, *Idaho.

The purpose of the research was to develop and apply methods for predicting daily irrigation diversions. Two types of models were developed to effectively predict diversions one day in advance and were applied to two large irrigation projects located in southeastern Idaho. The types of procedures developed and tested were (1) physical and (2) statistical procedures. In addition, variables related to predicting diversions were presented and their relationships described. The physical model developed was designed to accurately represent the physical processes of water conveyance and use in an irrigation system. Required inputs included crop consumptive use and irrigation efficiencies in conjunction with time variables such as irrigation interval, irrigation application time and traveling time in the system. Results from the physical model indicated that more data would be necessary for accurate predictions in addition to updating procedures to account for seasonal variations within the system and management. Statistical models were developed using multiple regression techniques. Required inputs included evapotranspiration, precipitation, weekly variation of water use, previous diversion, and dummy variables used to account for monthly and seasonal variations of soil moisture management. Predictions from the statistical model followed actual diversions quite closely for three irrigation seasons. It was concluded that the statistical models were superior to the physical modeling approach for predicting irrigation diversions.
W84-00045

A HEURISTIC SOLUTION PROCEDURE FOR A JOINT RESERVOIR CONTROL-CAPACITY EXPANSION PROBLEM,
National Research Inst. for Mathematical Sciences, Pretoria (South Africa).
M. Sniedovich, and P. A. Nielsen.
Water Resources Research, Vol 19, No 1, p 15-20, February, 1983. 7 Tab, 6 Ref.

Descriptors: *Reservoir operation, *Water supply systems, Optimization, Planning, Stochastic process, *Heuristic solution, Procedure.

The reservoir control-capacity expansion problem is treated by first solving a modified stochastic problem, then using simple heuristic methods to transform the optimal stochastic capacity expansion policy into a deterministic policy. This procedure avoids separating the problem into two sections and does not rely on steady state conditions. Since an optimal solution cannot be guaranteed, a procedure for constructing an upper bound for the optimal solution is given. This upper bound is used to evaluate the performance of the deterministic solutions and to determine whether the heuristic solution is nearly optimal. A numerical example illustrates the method. Water Resources Research, Vol 19, No 1, p 104-108, February, 1983. 4 Fig, 14 Ref.

Descriptors: *Flow regulation, *Reservoir releases, Reservoir operation, Markov process, Mathematical studies.

The asymptotic distribution of the maximum accumulated deficit with partially regulated, Markov-dependent net outflows having a Bernoulli distribution is derived, and the distribution for independent, continuous outflows is presented. It is demonstrated that under partial regulation the maximum deficit behaves as log n, where n is the length of the series; this is to be contrasted with the n to the 1/2 power behavior exhibited by fully regulated outflows. Also, as would be expected, the presence of correlation tends to increase the magnitude and variability of the maximum deficit. (Author's abstract)

DAILY OPERATION OF A MULTIPURPOSE RESERVOIR SYSTEM,
Southern Illinois Univ. at Carbondale. Dept. of Geology.
H. Yazicigil, M. H. Houck, and G. H. Toebes.
Water Resources Research, Vol 19, No 1, p 1-13, February, 1983. 11 Fig, 4 Tab, 13 Ref.

Descriptors: *Reservoir operation, *Model studies, *Decision making, Reservoir releases, Multipurpose reservoirs, Green River Basin, *Kentucky.

The Green River Basin Operation Optimization Model (GRBOOM) was designed to aid reservoir operators in making decisions for daily, real-time operations and for long-term operating guidelines. The Green River Basin, Kentucky, consists of four flood control reservoirs; recreation and low-flow augmentation are secondary objectives. The linear program model tries to minimize the sum of all daily penalties over the operating horizon (usually 1-5 days). Constraints include reservoir mass balance, storage zone, control station mass balance, flow zone, and release rate constraints. Simulation of reservoir operation using historical data for April 29, 1970, and for the 87-day period December 26, 1969-March 10, 1970, produced model-recommended operations that were 25.7% and 45.8%, respectively, more efficient than actual operations. The model is flexible and easily modified to allow experimentation with new operating regulations or policies. Results are produced in graphical form, if desired. (Cassar-FRC)

IMPROVEMENTS TO THE TRANSITION DEFINITION FOR THE LLOYD MODEL OF DISCRETE STATE STORAGE WITH CORRELATED INFLOWS,
New South Wales Univ., Kensington (Australia). School of Civil Engineering.
D. G. Doran.
Water Resources Research, Vol 19, No 1, p 69-76, February, 1983. 8 Fig, 30 Ref.

Descriptors: *Reservoir storage, *Storage, Model studies, Lloyd model.

The transition probability matrices which result from the Lloyd model of storage are very large, and when these matrices are constrained to be of manageable size, loss of accuracy in the performance of the model results. A description is given of an extension to a previous technique, the divided interval scheme, which makes possible the practical use of Markov chain analysis with given inflow distributions to provide comparatively accurate results in a probabilistic account of reservoir behavior. The extension is applied specifically to the Lloyd model of storage for single reservoirs, and the results of such analyses are obtained with modest computer storage requirements. (Author's abstract)

REAL-TIME RESERVOIR SYSTEM OPERATION,
Purdue Univ., Lafayette, IN. Water Resources Research Center.
M. H. Houck.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113661, Price codes: A04 in paper copy, A01 in microfiche. Technical Report No 151, September 1983. 42 p, 7 Fig, 2 Tab, 10 Ref. OWRT B-125-IND(2), 14-34-0001-1223.

Descriptors: *Reservoir operation, *Optimization, Flood routing, Streamflow forecasting, *Kentucky, Model studies, *Real-time operation, Goal programming, Objective function, Chance constrained programming, Green River Basin, Nonlinearity.

Several different optimization models developed by researchers at Purdue University for real-time, short term reservoir system operation are described. The models include: an optimization model constructed specifically for a multi-reservoir, multipurpose system in Kentucky; a goal programming model that requires less information than most other models yet yields equivalent or better results; a chance constrained model that explicitly considers errors in streamflow forecasts in the operating environment; and a balancing model that uses cumulative distribution functions to maintain a balance between storage, release, and any other characteristic of the operation. The description of each model and comparisons between models are brief but references to the relevant literature are provided.

POLDERS: AN ANCIENT APPROACH TO LAND RECLAMATION,
Rijkswaterstaat, The Hague (Netherlands).
A. Volker.
Nature and Resources, Vol 18, No 4, p 2-13, October-December, 1982. 6 Fig, 6 Ref.

Descriptors: *Polders, *Land reclamation, *Drainage, Agriculture, Developing countries, Deltas, Water management, Coastal engineering, Marshes, Hydraulic engineering, Netherlands, Japan, Tidal flats, Flood protection, History, Economic aspects, Irrigation, Risks.

Polders are a sophisticated form of land reclamation involving flood protection by embankment construction, water course diversion, or upstream flood control. Control of the water levels inside the polders produces land with high agricultural potential. Lands reclaimed by polders are level, often with heavy soils, and have a high water table. They may be formed along sea coasts, from coastal and inland marshes and lakes, in river valleys and by drying up to tidal inlets and lagoons. Some of the deepest polders are 6-10 m below mean sea level. Land subsidence from excessive groundwater abstraction is handled by polder construction. The deeper polders pose a risk to lives and property in case of unusually high water or embankment failure. Therefore, valuable and well-populated polder lands are designed for protection against a 10,000 year sea flood and a 1,000-3,000 year river flood. Warning systems, information programs, a backup line of defense, and drainage arrangements are also necessary. Drainage of polders should be accomplished by gravity if possible, using tidal variations, a lower river reach, or pumping. Polder-type retention basins were used for agriculture by the Egyptians 5000 years ago and by the Sumerians over 3000 years ago. The first Europeans to reclaim land by poldering were the Etruscans, 2500 years ago. In recent times the Netherland and Japan have been most active in polder construction, beginning independently in the late 16th century. Asia has the largest polder acreage, mainly in India and China. In Europe, coastal areas, lake and river deltas, and marshes have been reclaimed. Relatively few polders have been constructed in Africa. Total world polder area is on the order of 10-50 million ha. Future polder construction is expected to be concentrated in developing countries, especially near large cities. (Cassar-FRC)

PIPE DRAINAGE OF HEAVY SOILS: A FIELD EVALUATION,
Soil Conservation Service, Lincoln, NE.
P. N. Walker, and J. D. Wells.
Transactions of the ASAE, Vol 26, No 1, p 112-115, 122, 1983. 7 Tab, 5 Ref.

Descriptors: *Drainage, *Permeability coefficient, *Illinois, Subsurface drainage, Pipes, Irrigation.

Field effective hydraulic conductivities and drainable porosities were determined and drain spacings were recommended based on specified rates of water table fall. A group of 60 Illinois soils were selected for possible evaluation. Five were studied at sites where subsurface drain pipe systems had been installed previous to the study. Plots were irrigated to bring the water table to the soil surface. Irrigation was stopped, and then water table depth and drain flow measurements were made periodically until the water table midway between drains was at a depth of 300 mm. Drainable porosities, hydraulic conductivities, and recommended pipe drain spacings were computed. It was concluded that the average measured drainable porosities for Bonnie, Bryce, Darwin, Piopolis, and Wabash soils ranged from 0.0340 to 0.0483. The field effective hydraulic conductivities ranged from 19.0 to 63.2 mm/h. Only Bonnie had values with USDA published ranges; the other soils had higher measured values. The recommended drain spacings were: Bryce, 24.2 m; Bonnie, 13.9 m; Wabash, 12.8 m; Darwin, 10.8 m; and Piopolis, 13.1 m. (Baker-FRC)

SINGLE LOCATION DOUBLET WELL TO REDUCE SALT-WATER ENCROACHMENT: PHASE I - NUMERICAL SIMULATION,
Texas Water Resources Inst., College Station.
D. L. Reddell.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110873, Price codes: A04 in paper copy, A01 in microfiche. Technical Report No TR127, September 1983. 43 p, 6 Fig, 89 Ref. OWRT A-051-TEX(1), 14-34-0001-2146.

Descriptors: *Well doublet, Groundwater, *Numerical models, *Saline water encroachment, Well construction, *Simulation, Model studies, Water wells.

C. E. Jacob received patents in 1965 for a single location well doublet that would produce fresh water overlying salt-water without upconing of the heavier salt-water and pollution of the fresh-water zone. No known evaluation of the concept or development of design criteria has been accomplished. In this study, a finite difference radial flow model was developed to determine groundwater velocities and salt concentration as a function of time and space. This model was verified and is available for evaluating design criteria for Jacob's single location well doublet. Initial runs with the model indicate that the concept has potential, particularly in aquifers with clay lenses in the salt-water zone. Additional runs with the model will be needed to fully establish the design criteria necessary for Jacob's single location well doublet.

EFFECT OF PUMPED-WELL IRRIGATION AND DRAINAGE ON THE MELIORATION OF SALT-AFFECTED SOILS,
Academia Sinica, Nanjing (China). Nanjing Inst. of Soil Science.
Y. Wen-Rui, and W. Zun-Qin.
Soil Science, Vol 135, No 1, p 47-53, 1983. 2 Fig, 3 Tab, 4 Ref.

Descriptors: Soil properties, *Salinity, *Soil treatment, Drainage, Irrigation, *China, Groundwater, Groundwater management, *Saline soils.

In recent years benefits have been derived from well irrigation and drainage which were adopted for the improvement of salt affected soils in China. Well irrigation can simultaneously lower the groundwater level, leach salts downward from the soil, alleviate the harmful effects of flooding, and promote the salt-leaching effect of natural precipitation in areas where the groundwater is fresh or contains few minerals. Extraction and drainage of highly mineralized groundwater by wells can control the groundwater level and replenish the groundwater layer by irrigation with fresh water diverted from rivers in areas where the groundwater is highly mineralized. This will accelerate salt leaching from soil and prevent secondary salinization of the soil. However, ditch drainage cannot be replaced by well drainage, and usually a combination of the two should be adopted to improve soil quality. Three major patterns of well application for the improvement in soil quality in use in China are: a combination of well irrigation and well drainage in regions where the groundwater is fresh or contains only small amounts of minerals; a combination of deep and shallow wells in regions that have mineralized groundwater; and shallow well drainage in regions of highly mineralized groundwater. IMPROVED METHODS AND GUIDELINES FOR MODELING STORMWATER RUNOFF FROM SURFACE COAL MINED LANDS,
Kentucky Water Resources Research Inst., Lexington.
M. E. Meadows, and G. E. Blandford.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111731, Price codes: A06 in paper copy, A01 in microfiche. Research Report No 147, September 1983. 141 p, 21 Fig, 18 Tab, 64 Ref. OWRT B-069-KY(1), 14-34-0001-0222.

Descriptors: *Stormwater runoff, *Strip mines, Mathematical models, *Hydrologic models, *Synthetic hydrology, *Small watersheds, *Model studies, Simulation, Curve number, Unit hydrographs,

Kinematic runoff, Green-ampt infiltration, Finite element, Modified Newton-Raphson iteration, Excess rainfall pattern.

The investigations, developments and guidelines for several hydrologic modeling strategies are presented. Investigations were conducted to determine appropriate event curve numbers for surface mined disturbed watersheds; and performance of four synthetic unit hydrograph models (SCS curvilinear, SCS single triangle, Williams and TVA double triangle) on 38 USDA experimental watersheds in 14 physiographic provences using in excess of 270 events. A second test using only the SCS curvilinear unit hydrograph on 11 small watersheds and 48 events was conducted to investigate the excess rainfall simulated with the curve number model. A procedure for developing a unit hydrograph using the time area method and two parameter gama distribution is presented for ungaged watersheds or watersheds undergoing land use changes. The development of a coupled explicit finite difference Green and Ampt infiltration-implicit finite element kinematic water model is presented. The deterministic overland flow model includes a variable width which is essential for the accurate modeling of the watershed geometry. Both impervious and pervious watershed simulations are presented for the deterministic overland flow model.

A DECISION MODEL TO PREDICT SEDIMENT YIELD FROM FOREST PRACTICES,
National Forests in North Carolina, Asheville.
R. G. Burns, and J. D. Hewlett.
Water Resources Bulletin, Vol 19, No 1, p 9-14, February, 1983. 3 Fig, 1 Tab, 11 Ref.

Descriptors: *Sediment yield, *Model studies, *Forest management, Mathematical equations, Estimating equations, Decision making, Erosion, Erosion control, Forestry, *Georgia.

Forest managers need to predict sediment yield to perennial streams following various forest land operations in order to choose among best management practices. The universal soil loss equation (USLE) is not directly applicable to forest operations due to the heterogeneous soil surface conditions left by harvesting, site preparation, and planting. A sediment hazard index is proposed, to be based on the amount of exposed mineral soil and its proximity to streams. The model offered includes rainfall erosivity, soil erodibility, and average land slope, together with the index W. A paired watershed experiment in the central Georgia Piedmont was used to estimate parameters in the model. The experimental basin, 80 acres, was clearcut, drum roller chopped twice, and planted by machine. The standard error of estimate of the sediment yield was computed to be about 50 lb/ac per sampling period for four months. Use of Williams' erosivity index reduced the standard error to 33 lb/ac. It is suggested that the equations presented predict conservatively high for the normal range of expected rainfalls, but probably low under extreme rainfall. (Baker-FRC)

IMPACTS OF SILVICULTURE ON FLATWOODS RUNOFF, WATER QUALITY, AND NUTRIENT BUDGETS,
Florida Univ., Gainesville. Dept. of Forest Hydrology.
H. Riekerk.
Water Resources Bulletin, Vol 19, No 1, p 73-79, February, 1983. 4 Fig, 4 Tab, 16 Ref.

Descriptors: *Water quality, *Runoff, *Forest management, Hydrology, Silviculture, Flatwoods, Coastal areas, *Florida, Rainfall-runoff relationships, Nutrients.

Information is given on hydrology, water quality, and nutrient budgets for the first three years of a study on forest watersheds isolated by roads in poorly drained flatwoods of Florida. After 12 months of baseline calibration the forest in one watershed was harvested and regenerated with minimum disturbance, in the second watershed with maximum disturbance from common practices, and in the third watershed left intact as a control. Water yields from the maximum treatments increased a significant 250%, while that from the minimum treatments increased 117% as compared to the control. Weed vegetation remaining after the minimum treatment continued significant water use. The water yield increases lasted only for one year. Water quality was reduced by both treatments, with the most effect immediately after the maximum disturbance. Absolute levels of suspended sediments, potassium, and calcium remained relatively low. The maximum treatment caused significant changes in net cation balances only for one year. The information demonstrated relatively little effect of silvicultural practices in flatwoods on water quality as compared to data from upland forests. Water yield increases may be manipulated by the degree of harvest and weed control practices. (Baker-FRC)

ASPEN CLEARCUTTING INCREASES SNOWMELT AND STORM FLOW PEAKS IN NORTH CENTRAL MINNESOTA,
North Central Forest Experiment Station, Grand Rapids, MN. Forestry Sciences Lab.
E. S. Verry, J. R. Lewis, and K. N. Brooks.
Water Resources Bulletin, Vol 19, No 1, p 59-67, February, 1983. 5 Fig, 3 Tab, 36 Ref.

Descriptors: *Clearcutting, *Flood control, *Forestry, Aspen, Logging, Forest management, Watersheds, *Minnesota, Snowmelt, Rainfall-runoff relationships, Runoff, Storms, Rainfall.

An 18-year paired watershed study of rainfall and snowmelt response to clearcutting the upland part of an upland-peatland watershed in north central Minnesota is described. During the first year of this study one-half of the watershed was clearcut resulting in a 31% increase in annual water yield, but a 35% reduction in the size of snowmelt peak discharge. The nine-year response of peak discharge, storm flow volume, and timing of peak discharge following clearcutting are reported. Both snowmelt and rainfall runoff events are evaluated. Storm flow volumes from rain during the first two years increased as much as 170% but declined to preharvest volumes in the third year. Snowmelt volumes did not change significantly. Snowmelt peak discharge occurred about four to five days earlier after clearcutting, but the timing of storm flow from rainfall was not changed. Snowmelt peaks remained above precut size for nine years after clearcutting on the area undergoing natural regeneration to aspen saplings. Partial cutting - up to about one-half of the watershed - reduced peak snowmelt discharge because melt was desynchronized in cleared and forested parts. Clearing more than 2.3 of the watershed caused snowmelt flood peak size to double during the years with snow packs in excess of seven inches of water that remained until a day when temperatures exceeded 60 degrees F. SOIL EROSION CONTROL ON OWNER-OPERATED AND RENTED CROPLAND,
Missouri Univ.-Columbia. Dept. of Agricultural Economics.
D. E. Ervin.
Journal of Soil and Water Conservation, Vol 37, No 5, p 285-288, September/October, 1982. 3 Tab, 19 Ref.

Descriptors: *Erosion control, *Conservation, Farming, *Land management, Erosion, Management, Decision making, *Missouri, *Soil erosion.

Data from Monroe County, Missouri, are used to demonstrate that there is less erosion control on rented cropland than on cropland operated by the owner. Effective erosion control on rented cropland, therefore, will require special features in new conservation programs, such as differential cost-sharing provisions for tenants. The inclusion of a cost sharing program for erosion control in the original lease agreement appears to be an impo tant element. How to promote this type of lea should be an important area of study for state a federal soil conservation agencies. An importa first step would be to educate landlords and tena about the potential benefits of conservation pra tices an provsions that can be put into a lea Conservation tillage and contour farming would significant factors in alleviating the erosion pro lem. MODELING SURFACE AND SUBSURFAC STORMFLOW ON STEEPLY-SLOPING FO ESTED WATERSHEDS,
Kentucky Water Resources Research Inst., Le ington.
P. G. Sloan, I. D. Moore, G. B. Coltharp, and J. D. Eigel.
Available from the National Technical Informatic Service, Springfield, VA 22161 as PB84-11172 Price codes: A09 in paper copy, A01 in microfich Research Report No 142, July 1983. 182 p, 75 Fi 8 Tab, 90 Ref, 3 Append. OWRT A-085-KY(1 14-34-0001-1119(FY81), 14-34-0001-2119(FY82).

Descriptors: *Forest watershed, Forest hydrolog Mathematical models, Model testing, Subsurfac flow, Subsurface water, Runoff, *Surface flo Model studies, *Kentucky, Robinson Fores *Rainfall-runoff relationships, Macropore flo *Stormflow, Watershed models, Process model

A simple conceptual rainfall-runoff model, base on the variable source area concept, was deve oped for redicting runoff from small, steep-slope forested Appalachian watersheds. Tests of th model showed that the predicted and observe daily discharges were in good agreement. Th results demonstrated the ability of the model t simulate the 'flashy' hydrologic behavior of thes watersheds. Five subsurface flow models wer evaluated by application to existing data measure at Coweeta on a reconstructed homogenious fore soil. The five models were: Nieber's 2-D and 1-D finite element models, the kinematic wave equatio and two simple storage models developed by th authors, the Boussinesq and kinematic storag models. All five models performed reasonably we on this homogeneous soil. The coupled infiltratio model had a large effect on the simulation result The cost of running the computer models and th computer memory requirements increased as the complexity increased. Field soil-water and precipi tation measurements were made on a small te plot in Robinson Forest, in eastern Kentucky These data were used to calculate runoff durin four precipitation events and to test three of th subsurface flowmodels on a natural watershed The simple kinematic storage model performed th best. Flow from the test plot was dominated b macropore flow during storm events, and by flo through the soil matrix during baseflow or reces sion periods. No surface runoff was observed o the test plot during the period of field observa tions, except on saturated near-channel sourc areas.

CLIMATOLOGICAL WATERSHED CALIBRA TION,
Forest Research Inst., Kepong (Malaysia).
A. R. H. Nik, R. Lee, and J. D. Helvey.
Water Resources Bulletin, Vol 19, No 1, p 47-50 February, 1983. 2 Fig, 3 Tab, 5 Ref.

Descriptors: *Precipitation, *Streamflow, *Fores management, Water resources development, Wate supply, Water quality, Climate, Watersheds, Evap oration, *West Virginia, Appalachian Mountains Mountains.

The hypothesis that climatic data can be used t develop a watershed model so that streamflow changes following forest harvest can be deter mined was investigated. Variables which were measured included precipitation, daily maximum and minimum temperature, and concurrent relative humidity. Computed variables included humidity deficit, saturated vapor pressure, and ambient vapor pressure. The high degree of correlation

between annual precipitation and discharge suggests a linear relationship and implies similar watershed storages among hydrologic years. Thus annual discharge must be influenced more by seasonal factors such as precipitation and evaporative demand than by gross year to year differences in soil water storage. Moreover, whereas annual stream flow totals or averages are relatively steady, seasonal patterns of streamflow and the climatic variables of temperature and humidity deficit are obviously cyclic. This points directly to a deterministic relation between evaporation and streamflow and suggests the need for some adjustment to achieve functional synchronization of the seasonal cycles of precipitation and streamflow. It is concluded that climatological calibration appears to be a viable approach under special circumstances, such as when only one watershed is available for study. However, the paired watershed approach is expected to remain the preferred method for determining the effects of forest management on the water resource because of its simplicity and accuracy. 5A. Identification Of Pollutants

INVESTIGATION OF SURFACE WATER FOR CONTAMINATION WITH PSEUDORABIES VIRUS IN RUNOFF FROM PSEUDORABIES QUARANTINED NEBRASKA SWINE PRODUCTION AREAS,
Nebraska Univ.-Lincoln. Dept. of Veterinary Science.
C. L. Kelling.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110774, Price codes: A02 in paper copy, A01 in microfiche. Nebraska Water Resources Center Completion Report, September 1983. 10 p, 3 Tab, 24 Ref. OWRT A-071-NEB(1), 14-34-0001-2129.

Descriptors: *Animal diseases, *Viruses, Water pollution sources, Surface runoff, Waste disposal, Assay, Water analysis, Nebraska, *Pollutant identification, Molecular filtration, Pseudorabies virus.

The objective was to develop methods to concentrate water samples and quantitate virus and to apply the techniques to virological assay of storage ponds, lagoons, waste disposal sites and surface water runoff from swine production areas for contamination with pseudorabies virus. Molecular filtration has been used to concentrate pseudorabies virus (PRV; Herpevirus susis) from six liters of saline or water. Essentially all of the PRV added to the six liters of fluid was concentrated in 100 ml of filtration retentate. Inclusion of a cellulose acetate filter in the system effectively removed particulate matter without reducing the viral titer of the filtrate. The ability to remove particulate matter from water renders the system applicable to concentration of surface water runoff for assay for the presence of PRV. The capability to concentrate PRV from larger volumes of water will provide technology to assay runoff water from PRV quarantined swine production units for the presence of virus.
W84-00004

OLIGOCHAETES AS INDICATORS OF POLLUTION IN THE HUMBER ESTUARY, WITH SPECIAL REFERENCE TO TUBIFICOIDES BENEDENI,
Anglian Water Authority, Huntingdon (England). Lincolnshire River Div.
B. E. Barnett.
Environmental Pollution, Series A, Vol 30, No 4, p 277-291, 1983. 7 Fig, 1 Tab, 16 Ref.

Descriptors: *Water pollution effects, *Species diversity, *Oligochaetes, *Tubificids, *Bioindicators, *Distribution patterns, Industrial wastes, Indicators, Species composition, Domestic wastes, Coastal waters, Estuaries, Humber Estuary, *England.

Two intertidal surveys were conducted to examine the geographical and tidal distribution, abundance and numerical dominance of major oligochaete species in relation to the potential role of these organisms as indicators of pollution in the Humber Estuary, United Kingdom. Results showed that Tubifex costatus and Tubificoides benedeni were dominant species according to the Shannon-Weaver diversity index. Although data concerning oligochaete distribution and abundance must be interpreted with care, T. benedeni appears to be a valid indicator of pollution in the Humber. Two sites receiving considerable volumes of industrial and domestic effluents coincide with extreme dominance areas for T. benedeni and very low diversity values. T benedeni conducts its entire life cycle in the relative safety of the subsediment and exhibits a high tolerance for anoxia. These qualities make this tubificid oligochaete a genuine pollution indicator in the more saline reaches of estuaries and coastal habitats. (Geiger-FRC)

CANDIDA ALBICANS AS AN ALTERNATIVE SANITARY INDICATOR ORGANISM FOR WATERS CONTAINING ACID MINE DRAINAGE,
West Virginia Univ., Morgantown. Water Research Inst.
D. A. DePasquale, C. B. Law, and G. K. Bissonnette.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111814, Price codes: A03 in paper copy, A01 in microfiche. Water Research Institute Completion Report, 1983. 32 p, 7 Fig, 7 Tab, 40 Ref. OWRT A-047-WV(1), 14-34-0001-2152.

Descriptors: *Acid mine drainage, *Bioindicators, Indicators, Sanitary wastewater, *Survival, Water quality, *Yeasts, Bacteria, Coliforms, Domestic wastes, Enteric bacteria, Feces, Microorganisms, Mine drainage, Pathogens, Pollutant identification, Sewage bacteria, Streptococcus, Urine, Water pollution, Water pollution effects.

Microbiological studies were conducted to assess the potential of using Candida albicans as a sanitary-indicator organism in streams impacted by acid mine drainage (AMD) and organic wastes. C. albicans was detected at low densities in AMD, particularly when compared to the occurrence of traditional indicator bacteria. The relatively lower density of C. albicans in AMD was a reflection of its likewise low incidence in raw sewage. Pure-culture survival studies indicated that C. albicans is extremely resistant to the adverse effects of AMD as demonstrated by prolonged persistence of at least three days. In addition to its extended survival, C. albicans incurred minimal sublethal injury from AMD stress. Exposure of traditional indicator bacteria to identical conditions resulted in significant sublethal injury. The failure of standard microbiological procedures to detect AMD-damaged bacteria compromises the accuracy of assessing the public health safety of these waters. On the other hand, the marked resistance of C. albicans to injury lends support to its use as an alternative sanitary-indicator organism in streams containing acid mine drainage (AMD).

SODIUM HEXAMETAPHOSPHATE AS AN AID IN BENTHIC SAMPLE SORTING,
Central Electricity Generating Board, Southampton (England). Marine Biological Lab.
R. N. Bamber.
Marine Environmental Research, Vol 7, No 4, p 251-255, 1982. 2 Fig, 2 Tab, 4 Ref.

Descriptors: *Sampling, *Benthic environment, *Sedimentation, Sediments, Sodium hexametaphosphate, Sieving, Muds, Clays, Silts, Benthic fauna, Aquatic animals, Benthos, Fauna, *Pollutant identification, River Medway, England.

Since sieving problems had been experienced with fine estuarine muds occasionally exposed to erratic oil spillage in the River Medway, experimental analysis was undertaken to determine the efficacy of the addition of sodium hexametaphosphate to the initial fixative preservative for benthic samples. The presence of 1.24 g/liter sodium hexametaphosphate in the fixative solution was seen to significantly aid the disaggregation of fine sediment and thereby increase the efficiency of sieving benthic samples by some 23%. Concentrations greater than 1.24 g/liter do not significantly improve upon this performance. Observation of animal specimens from the samples subsequent to sieving demonstrated no inhibition of staining or fixation, and since the function of Rose Bengal staining is not critically dependent upon the precise color, proposed spectrophotometric analysis of the effect of the hexametaphosphate on the color of the stain was unnecessary. Foraminiferan shells were common in the samples and showed no evidence of degradation. The proportion of material passing through the sieve during the limited sieving time of the experiment when compared with the particle size structure of the inorganic sediment suggests that for these sediments at least, no extra treatment such as freezing is needed to further enhance the efficiency of sample sorting. Up to 90% of the treated samples passed the sieve, compared to an inorganic fraction of less than 0.5 mm of 96%. (Baker-FRC)

APPLICABILITY OF CERTAIN COMMON BIOINDICATION METHODS TO EVALUATION OF WATER QUALITY IN THE LITTORAL ZONE OF THE KREMENCHUG RESERVOIR,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
Yu. V. Pligin, and L. A. Zhuravleva.
Hydrobiological Journal, Vol 18, No 2, p 30-34, 1982. 2 Tab, 16 Ref.

Descriptors: *Eutrophication, *Reservoirs, *Bioindicators, Kremenchug reservoir, Water quality, Littoral zone, Benthos, Invertebrates, *USSR.

The eutrophication-induced changes in water quality in the littoral zone of the Kremenchug Reservoir were studied by means of bioindicator methods based on benthic invertebrates and hydrochemical indices. Macrozoobenthos and water were sampled for chemical analysis in five main shallow areas of the reservoir. Analyses were made of 360 quantitative samples of macrozoobenthos, collected in years with very hydrometeorological conditions. Six bioindicator procedures were evaluated, of which the systems of Goodnight and Whitley, King and Ball proved most applicable. The methods of Parele and Pantle and Bucca were less suitable, and those of Balushkina and Woodiwiss failed to work in this context. If macrozoobenthos analysis is to be used for water quality estimation, several procedures that would take into account as many species of invertebrates as possible should be jointly employed. Journal of Chromatographic Sciences, Vol 19, No 12, p 625-633, December, 1981. 8 Fig, 5 Tab, 17 Ref.

Descriptors: *Drugs, *Wastewater analysis, Sulfamethazine, Chemical analysis, Chromatography, Gas Chromatography, Trace levels, Pollutant identification, Feeds.

An electron capture gas chromatography method was developed for the determination of sulfamethazine, an antibacterial additive for animal feed, in wastewater at levels of 10 ppb. This toxic substance has the formula 4-amino-N-(4,6-dimethyl-2-pyrimidinyl) benzenesulfonamide. After cleanup by dichloromethane extraction, the samples were evaporated to dryness, methylated with diazomethane, acetylated with trifluoroacetic anhydride at the primary amine function, cleaned up on silica

gel, and assayed with electron capture gas chromatography. The compound was extremely stable in water. After 16 days storage at ambient temperature, solutions of 50 ppm and 500 ppm sulfamethazine yielded recoveries of 50 ppm and 496 ppm, respectively. (Cassar-FRC)

DETERMINATION OF TRACE AMOUNTS OF CHROMIUM (VI) IN PRESENCE OF SULFITE ION IN WASTEWATERS OF SURFACE TREATMENT (DETERMINATION DES TRACES DE CHROME (VI) EN PRESENCE DE SULFITE DANS LES EAUX RESIDUAIRES DE TRAITEMENT DE SURFACE),
Institut National de la Sante et de la Recherche Medicale, Paris (France).
P. Bourbon, J. Alary, J. -C. Lepert, and C. Balsa.
Analusis, Vol 9, No 3, p 110-112, 1981. 2 Fig, 6 Ref.

Descriptors: *Chromium, *Measurement techniques, *Trace levels, Heavy metals, Wastewater analysis.

Trace amounts of chromium (VI) cannot be determined in the presence of sulfite in wastewaters from surface treatment using the common techniques of spectrophotometry with diphenylcarbazide or atomic absorption after extraction with MIBK. A method of determination using pulse polarography is proposed. This method yields satisfactory results even in the presence of several metallic ions. Copper interferes with the method when its concentration exceeds 0.4 milligrams per liter and must be eliminated by precipitation at a pH of 9.5 to 10. The sensitivity of this method (20 micrograms of chromium (VI) per liter) is of the same order of magnitude as that achieved using the spectrophotometric method with diphenylcarbazide. In the absence of copper, the proposed method can also be used to determine the concentrations of some metallic ions, including cobalt, nickel, cadmium, and zinc, in the same sample. (Carroll-FRC)

IS ATP A SUITABLE BIOMASS PARAMETER FOR ACTIVATED SLUDGE. PART 1: THEORETICAL PRINCIPLES AND STATEMENT OF THE PROBLEM (IST ATP EIN GEEIGNETER BIOMASSE-PARAMETER FUR BELEBTE SCHLAMME. 1. MITTEILUNG: THEORETISCHE GRUNDLAGEN UND PROBLEMSTELLUNG),
Stuttgart Univ. (Germany, F.R.). Inst. fuer Siedlungswasserbau, Wasserguete- und Abfallwirtschaft.
E. Thomanetz, A. Sperandio, and D. Bardtke.
Gas- und Wasserfach: Wasser/Abwasser, Vol 123, No 2, p 96-101, 1982. 3 Fig, 24 Ref.

Descriptors: *Activated sludge process, *Adenosine triphosphate, *Metabolism, Activated sludge, Bacteria, Biomass, Microbiology, Bacterial analysis.

Methods of activated sludge biomass analysis are discussed. Since live bacteria cannot be quantified, the number of live cells, or the DNA content correlatable with it, would appear to be a suitable biomass parameter for viable numbers in activated sludges. However, a clear distinction must be made between viable numbers in sludges and the metabolic activity of such sludges. The essential biochemical properties and the possible reactions of ATP (adenosine triphosphate) are described. It is shown that, while ATP is clearly not suitable as a parameter for viable numbers of bacteria in activated sludges, it may conceivably be suitable--though possibly with certain reservations--as a parameter for the metabolic activity of these sludges. DETERMINATION OF TRACES OF SODIUM ALKYLBENZENESULPHONATE BY HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY. APPLICATION TO WATER,
Government Industrial Research Inst., Osaka (Japan).
T. Saito, K. Higashi, and K. Hagiwara.
Fresenius Zeitschrift Analytische Chemie, Vol 313, No 1, p 21-23, 1982. 3 Fig, 2 Tab, 5 Ref.

Descriptors: *Pollutant identification, *Chromatography, *Water analysis, *Alkylbenzenesulfonate, Ion exchange, Surfactants, High pressure liquid chromatography, Detergents.

High-performance liquid chromatography has been developed for the analysis of traces of alkylbenzenesulfonate in water. The method consists in the first stage of ion-exchange separation of dodecylbenzenesulfonate in water, and in the second stage, their determination by HPLC. The following conditions were employed: Shimadzu ZORBAX SIL Column (5 micrometers, 4.6 mm i.d. x 150 mm) as stationary phase, 0.2% ammonia-ethanol (v/v) as mobile phase, UV detector at 225 mm, injection volume 12 microliters. The chromatograms of alkylbenzenesulfonate (ABS) were simple and sharp, with a detection limit of 0.02 micrograms in 12 microliters of ethanol. Calibration curves of ABS were linear in a concentration range of 0.03 to 0.3 micrograms in 12 microliters of ethanol. In the case of linear sodium dodecylbenzenesulfonate positive errors of 1-4% were caused by nonionic surfactants or lauryl sulfate (6 fold excess); 10-50% positive errors were caused by 2-6 fold excess of household detergents. Standard water samples containing ABS were treated with a weak base anion-exchange resin; the adsorbed ABS were eluted and then determined either by HPLC or by the methylene blue spectrophotometric method. Recoveries of ABS in water were about 92-107% by HPLC. (Baker-FRC)

SIMULTANEOUS DETERMINATION OF HEAVY METALS IN WATERS BY INDUCTIVELY-COUPLED PLASMA ATOMIC EMISSION SPECTROMETRY AFTER EXTRACTION INTO DIISOBUTYL KETONE,
National Research Inst. for Pollution and Resources, Ibarkai (Japan).
A. Miyazaki, A. Kimura, K. Bansho, and Y. Umezaki.
Analytical Chimica Acta, Vol 144, p 213-221, 1982. 2 Fig, 4 Tab, 22 Ref.

Descriptors: *Pollutant identification, *Heavy metals, *Spectrophotometry, *Separation techniques, *Seawater, Chelating agents, Metal complexes, Cadmium, Lead, Zinc, Nickel, Copper, Iron, Molybdenum, Vanadium, Rivers, Water analysis, Metals.

The simultaneous determination of cadmium, lead, zinc, iron, copper, nickel, molybdenum and vanadium in river and sea water by inductively-coupled plasma atomic emission spectrometry was investigated. Diisobutyl ketone (DIBK) was used as solvent due to its low aqueous solubility and ease of introduction into the inductively-coupled plasma. The optimum observation height for the DIBK extract proved higher than that for an aqueous solution. Ammonium pyrrolidinedithiocarbamate (APDC) was used as chelating reagent at pH 2.4. The metals could be determined in samples at the microgram/liter level with detection limits ranging from 0.022 for cadmium to 0.60 for lead. The procedure should be applicable to other elements which form complexes with APDC. (Geiger-FRC)

TRACE METAL DETERMINATIONS IN ESTUARINE WATERS BY ELECTROTHERMAL ATOMIC ABSORPTION SPECTROMETRY AFTER EXTRACTION OF DITHIOCARBAMATE COMPLEXES INTO FREON,
Chalmers Univ. of Technology, Goeteborg (Sweden). Dept. of Analytical and Marine Chemistry.
L. G. Danielsson, B. Magnusson, S. Westerlund, and K. Zhang.
Analytica Chimica Acta, Vol 144, p 183-188, 1982. 3 Tab, 7 Ref.

Descriptors: *Heavy metals, *Pollutant identification, *Atomic absorption spectrophotometry, Salinity, Estuaries, Lead, Cadmium, Iron, Nickel, Zinc, Copper, Separation techniques.

The determination of cadmium, copper, iron, lead, nickel and zinc in estuarine waters by electrothermal atomic absorption spectrometry after extraction of dithiocarbamate complexes into freon is described. Samples of water are treated with 65% nitric acid and the dithiocarbamate complexes are extracted into Freon-TF and then back-extracted into dilute nitric acid solution. Portions of the back extracts are injected into a graphite furnace. A solution of mixed acetate buffer-complexing agent is used to eliminate the effect of high iron concentrations on the extraction procedure. The present method allows complete separation from the matrix irrespective of salinity and can be used throughout the full salinity range of an estuary. (Geiger-FRC)

5B. Sources Of Pollution

GROUNDWATER MONITORING AT A SEPTAGE LAGOON FACILITY,
Connecticut Univ., Storrs. Dept. of Agricultural Engineering.
J. Kolega, B. Morton, and H. Luce.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110758, Price codes: A02, in paper copy, A01 in microfiche. Institute of Water Resources Completion Report, September 1983. 14 p, 2 Fig, 3 Tab, 13 Ref. OWRT A-090-CONN(1), 14-34-0001-2107.

Descriptors: *Groundwater pollution, *Lagoons, Leachates, Septic sludge, Septic wastewater, Connecticut, Monitoring, Path of pollutants, Waste disposal.

A groundwater monitorng network was installed at a newly constructed earthen septage (septic tank pumpings) treatment and disposal facility at Coventry, CT to study the movement of chloride, nitrogen, trace metals, and hydrocarbons from the septage lagoons and their effect on groundwater quality. The facility was situated in a glacial outwash deltaic kame located adjacent to a floodplain wetland abutting the Willimantic River. The soil at the site was a glacial-fluvial deposit of sand typical of many river valley sections in southern New England. Groundwater elevations at the monitoring wells were measured prior to water sample collection along with the redox potential, salinity and the specific conductance. Sealing from the biomat formation at the septage-soil interface of the primary lagoon bottom did not occur nor did complete nitrification take place. Of the trace metals, cadmium, chromium, and lead were observed beneath the primary lagoon at concentrations which were above the adverse effect level for drinking water in the United States. Certain organohalides exceeded the recommended limits to protect human health.

STUDY OF MICROBIAL INACTIVATION IN THE MARINE ENVIRONMENT,
Malaga Univ. (Spain). Dept. of Microbiology.
J. J. Borrego, F. Arrabal, A. de Vicente, L. F. Gomez, and P. Romero.
Journal of the Water Pollution Control Federation, Vol 55, No 3, p 297-302, March, 1983. 2 Fig, 5 Tab, 19 Ref.

Descriptors: *Marine environment, *Bacteria, *Outfalls, *Wastewater disposal, Water pollution sources, Salmonella, Seawater, Escherichia coli, Pollution indicators, Monitoring, Spain, Aladino outfall, Bioindicators.

Microbial inactivation in the marine environment occurs by two different processes - physical dilution by diffusion, or a process of biological inactivation. Microbial inactivation was studied at the Aladino outfall, located off Carihuela beach, Spain, which discharges about 1,000 m from the coast. It consists of an 800 ml drainage pipe without terminal diffusors. The depth of discharge is about 19 m, and it is classified as a deep outfall because its

discharge forms a mixing layer of less than the total depth of the seawater. It has an irregular flow, depending on the time of day, with a maximum at 3 pm of 15 liters/second. The minimum is in the early morning. Data collected at the outfall show that most bacterial species underwent an initial dilution of over 90%. Salmonella-Shigella loses its viability most rapidly, perhaps because of poor adaptive capacity. However, the overall degrees of inactivation achieved, in descending order, are total coliform, fecal coliform, Salmonella-Shigella, coliphage, and fecal streptococci. Using Escherichia coli-specific bacteriophage as a pollution indicator is an attractive consideration, but more study is needed. (Baker-FRC)

DEGRADATION OF ATRAZINE IN ESTUARINE WATER/SEDIMENT SYSTEMS AND SOILS,
Salisbury State Coll., MD.
T. W. Jones, W. M. Kemp, J. C. Stevenson, and J. C. Means.
Journal of Environmental Quality, Vol 11, No 4, p 632-638, October-December, 1982. 5 Fig, 3 Tab, 28 Ref.

Descriptors: *Herbicides, *Sediment, *Degradation, *Fate of Pollutants, *Atrazine, Pesticides, Estuaries, Agricultural soils, Soils, Chesapeake Bay, *Maryland.

The fate of atrazine (2-chloro-4-ethylamino-6-isopropyl-amino-s-triazine) was studied in two estuarine water/sediment microsoms, using water from a protected Chesapeake Bay site and from an open bay site, and in two agricultural soil systems (sandy loam and silty loam). Experiments were done under both aerobic and anaerobic conditions. Half-lives for atrazine were: water, 3-12 days (faster in open water samples than in protected site samples); sediments, 15 and 20 days; and soils, 330 and 285 days. These half-lives were based on the assumption that the ratio of atrazine and metabolites in the nonextractable portion was the same as in the extractable portion. Low oxygen conditions had littleeffect on the rate of atrazine degradation. The major short-term metabolite of estuarine and soil systems was hdroxyatrazine (2-hydroxy-4-ethylamino-6-isopropylamine-s-triazine). (Cassar-FRC)

FOOD CHAIN ENRICHMENT OF ORGANOCHLORINE COMPOUNDS AND MERCURY IN CLEAN AND POLLUTED LAKES OF FINLAND,
Jyvaeskylae Univ. (Finland). Dept. of Chemistry.
J. Paasivirta, J. Sarkka, K. Surma-Aho, T. Humppi, and T. Kuokkanen.
Chemosphere, Vol 12, No 2, p 239-252, 1983. 3 Fig, 9 Tab, 14 Ref.

Descriptors: *Food chains, Enrichment, *Lakes, *Finland, Fish, *Mercury, *Organochlorines, Pulp and paper industry, *Pulp wastes, Chlorinated hydrocarbons, Phenols.

A new sampling and analysis program was constructed for determining contents of mercury and chlorinated hydrocarbons and chlorinated phenols in different trophic levels of lakes in central Finland. The lakes under study are polluted by pulp mill and urban wastes. They contain pulp chlorine bleaching residues, mercury, methyl mercury, and organochlorine compounds in sediment, plankton, roach and pike. A 30-fold increase in mercury in bottom sediments has resulted from chlorine bleaching agents dumped in the lakes. This was not reflected in mercury levels in fish, which were highest at one natural condition (humic) lake and rather high also in semipolluted lake Paijanne. Mercury in fish was mostly methylated, but not completely, and its time trends could be estimated. Chloroform showed no bio-accumulation in fish. Carbon tetrachloride, tetrachloroethylene and chlorinated cymenes significantly bioaccumulated in fish. Levels of chlorophenols from bleaching had strongly decreased, but pentachlorophenol and 2,3,4,6-tetrachlorophenol levels remained related to earlier results. The present results show that although sediment seems to serve for storage of certain persistent biocides, the contents in bottom sediments do not directly reflect the contents in biota. (Baker-FRC)

THE EVALUATION OF METALS AND OTHER SUBSTANCES RELEASED INTO COAL MINE ACCRUAL WATERS ON THE WASATCH PLATEAU COAL FIELD, UTAH,
Utah Water Research Lab., Logan.
A. J. Seierstad, V. D. Adams, V. A. Lamarra, N. J. Hoefs, and R. E. Hinchee.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111681, Price codes: A08 in paper copy, A01 in microfiche. Water Quality Series UWRL/Q-83/09, August 1983. 156 p, 30 Fig, 46 Tab, 68 Ref, 1 Append. OWRT B-210-UTAH(2), 14-34-0001-1273.

Descriptors: Coal, Coal mining, *Coal mines, *Leachates, Boron, Strontium, Water pollution control, Iron, *Acid mine drainage, Alkalinity, Mercury, Suspended solids, Grease, Hardness, Filtered wastewater, *Utah, Wasatch Plateau, *Metals.

In the face of probable coal mining expansion on the Wasatch Plateau of Central Utah, threats to drinking water safety and healthy aquatic environments were examined by reviewing reports submitted by mine operators as required by the National Pollution Discharge Elimination System, measuring pollutant concentrations in mine accrual waters before and after treatment, and analyzing experimental leachates obtained by upward flow of waters (prepared to match average natural conditions) through crushed coal in laboratory columns. The reports, mine accrual waters, and leachates covered six mines, four of which continually discharged water, and two of which were collecting water internally. One sump is being used for drinking water supply. Sampling continued from April 1981 through May 1982. Constituents measured and compared with water quality criteria for drinking, irrigating, stock watering, and aquatic resources included pH, suspended solids, metals, hardness, alkalinity, and silica. Generally, the waters did not exceed toxicity criteria, and concentrations leached from crushed coal samples provided a reasonable guide to concentrations measured in the accrual waters. Boron concentrations were occasionally high enough to affect sensitive crops. Mercury seldom exceeded standards but was generally close enough to deserve special monitoring and analysis for possible environmental effects. Acidity and iron were not a problem, but total suspended solids as well as oil and grease often were. The existing treatment by gravel filtration ponds and grease skimming devices was not very effective. Overall, the results did not find a significant pollution problem, identified potential hazards, and provided more cost effective pollution control information.

EVALUATION OF THE POTENTIAL FOR GROUNDWATER TRANSPORT OF MUTAGENIC COMPOUNDS RELEASED BY SPENT OIL SHALE,
Utah Water Research Lab., Logan.
R. E. Hinchee, V. D. Adams, J. G. Curtis, and A. J. Seierstad.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111699, Price codes: A07 in paper copy, A01 in microfiche. Water Quality Series UWRL/Q-83/06, July 1983. 127 p, 23 Fig, 22 Tab, 150 Ref, 2 Append. OWRT B-210-UTAH(1), 14-34-0001-1273.

Descriptors: *Carcinogens, *Bioassay, Coal, *Oil shale, *Leachates, Water pollution sources, Groundwater pollution, Organic carbon, *Mutagenic compounds, *Utah, Wasatch Plateau, Anvil Points, *Retort processes.

The potential mutagenicity of aqueous leachates from coal, raw oil shale, and the spent shale resulting from two processes was tested. Specifically, an Ames salmonella microsomal bioassay was used to test for chemical mutagenicity. Spent oil shales from the Paraho and TOSCO II processes, a raw shale from Anvil Points, and a composite coal sample from Wasatch plateau were extracted with double deionized water and organic solvents. Of the tests, only organic solvent extraction of the TOSCO spent shale resulted in a mutagenic response. The lack of mutagenic response to organic extracts of Paraho spent shale was unexpected and probably due to high temperatures at which the shale had been retorted. By using a TOSCO spent shale leachate and an organically extracted mutagen, a partition relationship was developed between the spent shale and leachate water. A discovered high affinity of the mutagen for spent shale was believed to minimize amounts getting into the leachate. Consequently, it was estimated that the mutagenicity of spent shale leachate will be low (in the range of that of chlorinated wastewater). However, the large volumes of water required to complete the leaching of the mutagens from the pile are likely to create a chronic long-term problem.

HERBICIDES IN RUNOFF FROM AGRICULTURAL WATERSHEDS IN A HIGH-WINTER-RAINFALL ZONE,
Oregon State Univ., Corvallis. Dept. of Soil Science.
J. S. Hickman, M. E. Harward, and M. L. Montgomery.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111772, Price codes: A06 in paper copy, A01 in microfiche. Water Resources Research Institute Publication WRRI-86, Oregon State Univ., Corvallis, September 1983. 107 p, 19 Fig, 8 Tab, 95 Ref, 1 Append. OWRT B-075-ORE(1), 14-34-0001-0276.

Descriptors: *Herbicides, *Agricultural runoff, *Diclofop-methyl, *Diclofop, Hydrolysis, Chemical degradation, Leaching, *Trifluralin, Subsurface drainage, Stream pollution, Soil properties, *Agricultural watersheds, Path of pollutants, *Oregon, Williamette Valley.

Runoff losses were quantified for two herbicides from fall-planted agricultural watersheds in the Williamette Valley, Oregon. Factors and processes influencing herbicide transport were indentified. Diclofop runoff losses were measured following a January application (1.12 kg/ha) of diclofop-methyl. Diclofop-methyl rapidly hydrolyzed to diclofop ($t1/2<1$ day), while degradation beyond the diclofop molecule was much slower ($t1/2=42$ days). Runoff losses were 7.1 and 3.9% of the applied herbicide in 1980 and 0.7 and $<0.1\%$ in 1981 at a 6.0 ha and 1.4 ha (subsurface drained) watershed, respectively. The maximum diclofop concentrations were 370 and 790 mg/m super 3 at the two watersheds, respectively. More than 80% of the diclofop loss was partitioned into the aqueous phase of runoff. Runoff losses of trifluralin following a 0.84 kg/ha October 1979 application were 0.9 and $<0.1\%$ and maximum concentrations were 216 and 9.5 mg/m super 3 at the 6.0 and 1.4 ha watersheds, respectively. Lowere runoff losses of both herbicides at the 1.4 watershed were attributed to the effectiveness of the subsurface drainage system (a potential management practice) in reducing antecedent soil moisture. Herbicide losses in the subsurface drainage effluent accounted for 1.2 and $<0.1\%$ of the applied diclofop in 1980 and 1981, respectively, and $<0.1\%$ of the applied trifluralin. Major factors affecting herbicide runoff losses were (1) proximity of the first runoff event to the application date, (2) soil moisture status before and during storm events, (3) magnitude of the precipitation events, and (4) formation of a soil crust.
W84-00037

NATURE OF PHOSPHORUS FRACTIONS IN LAND RUNOFF AND THEIR AVAILABILITY TO ALGAE,
Cornell Univ., Ithaca, NY.
J. P. Barlow, D. R. Bouldin, R. T. Oglesby, W. R. Schaffner, and M. S. Glase.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111830, Price codes: A04 in paper copy, A01 in microfiche. Center for Environmental Research Completion Report, (1983). 63 p, 15 Fig, 11 Tab, 15 Ref. OWRT B-098-NY(1), 14-34-0001-1251.

Descriptors: *Phosphorus, *Biological availability, *Algal assay, Reactive phosphorus, Organic phosphorus, Sorption, Particulate phosphorus, Soil nutrient losses, *Agricultural runoff, New York.

Phosphorus in agricultural discharge and streams was examined for biological availability of soluble fractions and for the quantity of these in discharge. In streams, very little soluble P was detected, even during heavy flow. Although there was considerable variability in the concentration of P discharged from fields, the total amount lost was closely related to the amount of water discharged. Soluble P, both molybdate reactive and unreactive was largely biologically available as determined by algal bioassays and bioassays using natural pond microfloral assemblages. Soluble P which was less available after herbicide treatment or frosts may have resulted from breakdown of plant material. Sorption reactions during mixing of field discharge with stream water were estimated by adding increasing amounts of low P water to discharge water. Generally, soluble molybdate reactive P was absorbed and decreased in concentration while soluble unreactive P was desorbed and increased in concentration. Sorption was related to the quantity of suspended particulates.
W84-00043

TRACE METALS IN SEDIMENTS OF THE ST. JONES AND MURDERKILL RIVERS, DELAWARE,
Delaware Univ., Newark. Coll. of Marine Studies.
D. Hoffman, and R. Biggs.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111897, Price codes: A02 in paper copy, A01 in microfiche. Water Resources Center Completion Report, September 1983. 14 p, 2 Fig, 4 Tab, 2 Ref. OWRT A-055-DEL(1), 14-34-0001-2108.

Descriptors: *Trace metals, *Sediments, *Estuaries, *Delaware, Water chemistry, St. Jones River, Murderkill River, Copper, Cadmium, Zinc, Chromium, Iron, Lead, Manganese, Pollutant identification, Water pollution sources.

The metals Cu, Cd, Cr, Zn, Fe, Mn, Pb were analyzed from surface sediments from 47 locations in the Murderkill and St. Jones Rivers, Delaware. Prior to 1976, the St. Jones received domestic sewage from the City of Dover, Delaware. A regional sewage plant began operations in 1976 and discharged the combined wastes from Dover and surrounding areas into the Murderkill. Results of the 1982 metals survey were compared with data obtained by the same authors at the same locations in 1973. Cu, Cd, and Pb show higher concentrations in Murderkill bed sediments in 1982 than in 1973. These concentrations decrease in the mainstem river away from the STP discharge points. Cr, Fe, and Mg do not show such excursions and are indistinguishable from the 1973 concentrations. Metal concentrations in bed sediments of the St. Jones River show no change for 1973 to 1980, except that Pb, Cd and Zn sediment concentrations are generally lower in 1982. The analyses suggest that Cu, Cd, and Pb are increasing in the sediments from the Murderkill while Fe, Mn, and Cr are not. Pb, Cd, and Zn are decreasing in the St. Jones sediments, perhaps because they are being leached from the sediments or because they are being buried and diluted with clean materials.

METAL LOADING OF THE B. EVERETT JORDAN RESERVOIR,
North Carolina Univ. at Chapel Hill. Dept. of Environmental Sciences and Engineering.
M. S. Shuman, K. G. Robinson, and C. E. Stokes.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111913, Price codes: A04 in paper copy, A01 in microfiche. Report No 200, July 1983. 60 p, 7 Fig, 14 Tab, 30 Ref. OWRT A-112-NC(1), 14-34-0001-1135.

Descriptors: Metals, *Heavy metals, Zinc, Cadmium, Lead, Copper, Mercury, Streams, Rivers, *Reservoirs, Streamflow, Low flow, High flow, Suspended sediments, Particulate matter, Dissolved solids, Particle size, Municipal wastewater, Urban runoff, *North Carolina, B. Everett Jordan Reservoir.

Filterable and non-filterable Zn, Cd, Pb, Cu and Hg concentrations were examined in streams which form the B. Everett Jordan Reservoir, N.C. Stream samples were collected to coincide with low and high flow events. Zinc, Cu, Pb and Hg were transported principally in the non-filterable fraction and at high flow, whereas less than 20% of the Cd was transported in that fraction. Metal loadings were estimated from flow-weighted mean metal concentrations and mean stream flow data and indicated the importance of sampling during high flow events. Metal concentrations at high flow depended less on flow magnitude than the time relative to peak flow when the sample was collected. The order of metal loading was Zn>Cu>Pb>Hg with the industrialized Haw River sub-basin contributing more metals Zn (19.7 X 10 super 3 g/km super 2-yr), Cd (32.4 X 10 super 1 g/km super 2-yr), Pb (5.0 X 10 super 3 g/km super 2-yr), Cu (8.8 X 10 super 3 g/km super 2-yr), and Hg (4.2 X 10 super 1 g/km super 2-yr)), Pb (1.4 X 10 super 3 g/km super 2-yr) Cu (2.1 X 10 super 3 g/km super 2-yr) and Hg 2.5 g/km super 2-yr).

TRANSPORT OF POLLUTANTS IN NATURAL STREAMS,
Windsor Univ. (Ontario). Dept. of Civil Engineering.
J. A. McCorquodale, E. H. Imam, J. K. Bewtra, Y. S. Hamdy, and J. K. Kinkead.
Canadian Journal of Civil Engineering, Vol 10, No 1, p 9-17, 1983. 4 Fig, 12 Ref.

Descriptors: *Organic compounds, *Industrial wastes, *Outfalls, Fate of pollutants, Model studies, Mathematical models, Mixing, St. Clair River, *Ontario, Rivers, Dispersion, *Path of pollutants.

Dispersion of soluble degradable and nondegradable pollutants discharged from multiple industrial sources into a large river was simulated by a two-dimensional mathematical model. The Akhtar (1978) model was modified to include the effect of depth and velocity variations in both longitudinal and lateral directions, the effect of rapid convergence or divergence of stream width, lateral convection of mass, the effect of flow diversion, the effect of jet mixing and dilution at shore-based and extended outfalls, and the removal rates of degradable trace organic pollutants. The model is divided into two parts: the river hydrodynamics model and the pollutant transport model. The model was validated by using phenol as a pollutant and comparing model results with observed data obtained from the St. Clair River, Ontario. A simulation using effluent discharges from 24 sources at 19 different locations produced results for phenol, benzene, toluene, methylene chloride, and carbon tetrachloride the agreed well with measured concentrations of the chemicals in river water. It was observed that pollutants disperse slowly when discharged in a shallow, slow-moving zone of the river and disperse rapidly once they reach the deeper water. The deeper the outfall, the faster the lateral dispersion of pollutants into the river. (Cassar-FRC).

WASTE-RELATED CADMIUM CYCLE IN SWITZERLAND,
Eidgenoessische Anstalt fuer Wasserversorgung, Abwasserreinigung und Gewaesserschultz, Duebendorf (Switzerland).
L. Keller, and P. H. Brunner.
Ecotoxicology and Environmental Safety, Vol 7, No 1, p 141-150, 1983. 6 Fig, 6 Tab, 14 Ref.

Descriptors: *Cadmium, *Fate of pollutants, *Land disposal, *Spatial distribution, *Bioaccumulation, *Composting, *Sludge disposal, Heavy metals, Landfills, Soil amendments, Leaching, *Switzerland.

In Switzerland, an average of 120 tons of cadmium are used each year. Of this amount, an estimated 25 tons end up in municipal solid waste, 3 tons in wastewater, and 19 tons in precipitation and dry fallout. About 40 tons of cadmium annually are deposited directly to the soil via landfills, the atmosphere or the fertilization of agricultural land. Theoretically, the cadmium content of the soil may double in 150 years, thus increasing the cadmium content of plants grown on such soil. Model studies predict that soil cadmium levels should not exceed 3 ppm. At such levels, plants are likely to attain cadmium levels > 0.4 milligrams/kilogram, a concentration which can cause toxic effects in long term experiments. Since cadmium is not distributed evenly over Switzerland, the use of compost may render many soils unfit for the production of crops intended for human consumption in only 14 years. For sewage sludge application to cropland, this time span is 130 years. In a steady state, the cadmium input to soil should equal its output via plants, leachate, and erosion. The dissipative use of cadmium must be stopped if heavy metal limits in food are to be observed. (Geiger-FRC)

POLLUTANT-PARTICLE ASSOCIATIONS AND DYNAMICS IN COASTAL MARINE ENVIRONMENTS: A REVIEW,
Oak Ridge National Lab., TN. Environmental Sciences Div.
C. R. Olsen, N. H. Cutshall, and I. L. Larsen.
Marine Chemistry, Vol 11, No 6, p 501-533, 1982. 8 Fig, 182 Ref.

Descriptors: *Estuarine environment, *Water pollution sources, *Sedimentation, Dynamics, Coastal waters, *Reviews, Chemical reactions, Sediment transport, Fate of pollutants.

This review indicates that many pollutants rapidly become associated with particles in coastal marine environments and that these particles are then effectively trapped in the estuaries. This association may result from ionic sorption and flocculation, organic complexation and flocculation, hydrophobic interactions with particle surfaces, bio-aggregation, or sorption and co-precipitation with Mn-Fe hydroxides. The net transport of particles and associated pollutants is downstream in the lower salinity surface layer of an estuary, but as these particles settle to the more saline bottom they may be transported back upstream and trapped by estuarine circulation. The rate of particle-pollutant deposition is generally high and is governed to a great extent by estuarine sedimentary processes. Several processes such as sediment resuspension, diffusion from anoxic sediments, and dredging-dumping operations can reintroduce pollutants to marine waters which had already settled out. Dissolved nutrients that may escape an estuary stimulate productivity in near-shore coastal waters and are rapidly removed by biological processes, frequently forming plankton plumes at estuary mouths. Major removal mechanisms for pollutants in shelf waters include sorption onto resuspended sediments, incorporation into living organisms and sinking of

organic debris or boundary-layer scavenging in association with the redox cycling of Mn-Fe hydroxides. Of prime importance in any predictive model is a quantitative understanding of the rates associated with the biogeochemical processes that affect pollutant-particle dynamics. These process-oriented transfer rates include: input rates into the marine environment, exchange rates across the air-sea interface, transport rates in the water column, and transfer into and out of the sediments. Quantitative values for the above transfer rates are needed to determine particle-pollutant fluxes and define how long a pollutant will persist. (Baker-FRC)

MICROBIOLOGICAL CONDITIONS AND WATER QUALITY IN THE LOWER DNIEPR,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
E. Ya. Rossova, T. G. Moroz, R. A. Kokoreva, G. N. Shakhman, and T. L. Aleksenko.
Hydrobiological Journal, Vol 18, No 2, p 52-57, 1982. 5 Fig, 1 Tab, 12 Ref.

Descriptors: Water quality, *Bioindicators, Lakes, Dniepr River, Rivers, *Water quality control, Indicators, Microbiological studies, Bacteria, Seasonal variation, Bacterioplankton, *USSR.

The microbiology of the lower Dniepr was investigated and its water quality evaluated based on microbiological, hydrobiological and hydrochemical properties. The decomposition of organic matter and the self-purification of water occurred at the highest rates in the branches of the Dniepr within the city of Kherson in spring and summer. The degree of pollution and water quality of various sections of the lower Dniepr varied by seasons. Above and below Kherson, the Dniepr in all seasons except summer is pure or only slightly polluted (oligo-saprobic water). In summer the water is of lower quality (oligo-beta-mesoprobic). In general, the lower Dniepr is pure or only moderately polluted, but its branches within the city are moderately or strongly polluted (beta-alpha-mesosaprobic). (Baker-FRC)

PETROLEUM HYDROCARBONS IN SEDIMENTS OF SOUTHAMPTON WATER ESTUARY,
Bermuda Biological Station for Research, St. George's West.
A. H. Knap, P. J. Leb, P. J. L. Williams, and E. Lysiak.
Marine Environmental Research, Vol 7, No 4, p 235-249, 1982. 4 Fig, 6 Tab, 29 Ref.

Descriptors: *Industrial wastes, *Sedimentation, *Estuaries, Southampton, Refineries, Petroleum industry, Petroleum hydrocarbons, Water pollution sources, Fate of pollutants, *England.

Components of the total carbon cycle in Southampton Water have been investigated. Southampton Water estuary is a typical coastal plain estuary formed from the drowned lower portions of the Test and Itchen Rivers. About 75% of the total industrial discharge to the estuary is from a refinery. The non-volatile input ranges from 1 to 2 tons per day. Data indicate that the industrial outfalls on the southwestern bank of the estuary may be regarded as a substantial point source. Surface sediment hydrocarbon concentrations in the vicinity of the refinery were in the region of 1-3 mg C/g dry weight, falling to 0.5 mg C/g or less at a distance from the refinery. In the vicinity of the refinery Pb-210 dating of a core suggested a very high sedimentation rate, with a petroleum hydrocarbon horizon deeper than 3.5 m in at least one case. In another core, elevated hydrocarbon concentrations at 50-70 cm depth coincided well with elevated copper concentrations at those depths. The hydrocarbon concentrations in surface sediments distant from the refinery were not considered high in relation to other industrialized estuaries, thus demonstrating the importance of sediment adsorption as a mechanism of deposition of petroleum hydrocarbons close to the source. THE KINETICS OF THE OXIDATION OF FERROUS IRON IN SYNTHETIC AND NATURAL WATERS,
Freshwater Biological Association, Windermere (England).
W. Davison, and G. Seed.
Geochimica et Cosmochimica Acta, Vol 47, No 1, p 67-79, 1983. 5 Fig, 4 Tab, 50 Ref.

Descriptors: *Kinetics, *Iron, *Oxidation, Surface waters, Seasonal variations, Acidity, Particulates, Chemical reactions, Lakes, *Fate of pollutants, Laboratory studies, Anoxic conditions, *England, Esthwaite Lake.

The rate of oxidation of ferrous iron in natural waters was measured in the laboratory under conditions which were as close as possible to natural. Verification of the rate law by investigating the effect of pH, partial pressure of oxygen, and the influence of natural solid phases and changing microbial populations was attempted while maintaining natural conditions. Anoxic water samples were collected from the hypolimnion of a seasonally anoxic lake, Esthwaite Water in the English Lake District, on different days during the summer period of anoxia. The data were consistent with the simple rate law for homogeneous chemical kinetics previously established for synthetic solutions. The rate constant for the oxidation reaction in lake water was indistinguishable from that measured in synthetic samples. It did not appear to be influenced by changes in the microbial populations or by changes in any particulate or soluble components in the water, including iron and manganese. Analysis of the errors inherent in kinetic measurements showed that the estimation of pH was the major error source and that values of the rate constant determined by different workers could easily differ by a factor of six. A universal rate constant is suggested for natural freshwaters in the pH range 6.5 to 7.4. Discrepancies in the effects of ionic strength and interfering substances reported in the literature are highlighted. Generally substances have only been found to interfere at concentrations which far exceed those in most natural waters. (Baker-FRC)

SOURCES, SINKS, AND DISTRIBUTION OF ORGANIC CARBON IN THE ST. LAWRENCE ESTUARY, CANADA,
Bedford Inst. of Oceanography, Dartmouth (Nov Scotia). Atlantic Oceanographic Lab.
F. C. Tan, and P. M. Strain.
Geochimica et Cosmochimica Acta, Vol 47, No 1, p 125-132, 1983. 2 Fig, 5 Tab, 19 Ref.

Descriptors: *Sinks, *Estuaries, *Organic compounds, Carbon, Water pollution sources, Plankton, Sedimentation, Rivers, Gulf of St. Lawrence, Canada, St. Lawrence Estuary, Path of pollutants.

The sources and sinks of the organic carbon in the St. Lawrence Estuary and Gulf of St. Lawrence in Canada were investigated by carbon isotope ratio analysis of particulate, planktonic, and sedimentary organic carbon and dissolved inorganic carbon. In the upper St. Lawrence Estuary particulate organic carbon (POC) isotope ratios are uniform and indistinguishable from those of POC in the St. Lawrence River and of planktonic organic carbon in both areas. The abundance of freshwater diatoms in the upper Estuary suggests that upper Estuary POC is mainly fresh organic matter of riverborne origin. Upper estuary POC is isotopically different from POC in the lower St. Lawrence estuary and Gaspe regions, but is not different from POC from the surface waters of the open Gulf of St. Lawrence. The isotopic composition of planktonic organic carbon mirrors that of the POC, indicating that the POC in the lower estuary is also fresh organic matter. Since the lower estuary POC forms an isotopic barrier between the upper estuary POC and the Gulf of St. Lawrence POC, there appears to be little mixing of POC between these three reservoirs. Therefore POC in the lower estuary and gulf is most likely both produced and deposited in situ. The isotope ratio differences between the planktonic and dissolved inorganic carbon reservoirs shows that the difference varies significantly and somewhat unpredictably between sectors of the area studied. Thus one must use caution in assuming a constant fractionation factor and in applying such a factor to the interpretation of carbon isotope data. (Baker-FRC)

LEVELS OF HEAVY METAL POLLUTANTS IN TWO SPECIES OF MARINE NEMATODES,
Newcastle upon Tyne Univ. (England). Dept. of Zoology.
R. Howell.
Marine Pollution Bulletin, Vol 13, No 11, p 396-398, 1982. 1 Fig, 3 Tab, 19 Ref.

Descriptors: *Nematodes, *Metals, Fate of pollutants, Invertebrates, Heavy metals, Copper, Zinc, Lead, Cadmium, Mercury, Budle Bay, Blythe Estuary, Tees Estuary, *United Kingdom, Enoplus, Benthic fauna, Estuaries.

Heavy metals were determined in two nematode species collected from three sites on Britain's northeast coast: Budle Bay (nonpolluted), Blythe Estuary (significantly polluted), and Tees Estuary (extensively polluted). Mean metal concentrations (ppm) in Enoplus brevis at the 3 sites were: Cu, 61-245; Zn, 147-649; Pb, 20-42; Cd, 8-11; and Hg, 0.15-0.96. Mean metal concentrations (ppm) in Enoplus communis were: Cu, 33-60; Zn, 105-1865; Pb, 14-37; Cd, 5-51; and Hg, 0.11-1.22. Metals levels were lowest in Budle Bay and highest in Tees Estuary, except for Pb and Hg in E. brevis and Zn and Cd in E. communis. (Cassar-FRC)

AN ASSESSMENT OF MARINE POLLUTION IN PUGET SOUND,
National Oceanic and Atmospheric Administration, Seattle, WA. Office of Marine Pollution Assessment.
E. R. Long.
Marine Pollution Bulletin, Vol 13, No 11, p 380-383, 1982. 1 Fig.

Descriptors: *Organic compounds, *Metals, *Marine animals, Fate of pollutants, Puget Sound, Washington, Aromatic hydrocarbons, Water pollution effects, Fish, Pesticides, Chlorinated hydrocarbons, Marine Ecosystems Analysis Report, *Washington.

Selected results of the Marine Ecosystems Analysis Puget Sound project, initiated in 1978, are reported. Routinely analyzed were 27 aromatic hydrocarbons, 13 chlorinated pesticides, 37 metals, polychlorinated biphenyls (PCB), and chlorobutadienes in sediments and organisms. The highest mean contaminant levels in sediments and sole livers, respectively, were: PCB, 380 ppb and 35,000 ppb; total chlorobutadienes, 1600 ppb and 9100 ppb; hexachlorobenzene, 74 ppb and 3700 ppb. Total aromatic hydrocarbons levels reached a high of 13,000 ppb (mean value). Highest trace metals concentrations were: Hg, 1900 ppb; Pb, 630,000 ppb; As, 470,000 ppb; and Cd, 18,000 ppb. A large variety of histopathological conditions were observed among fish, shrimp, and crabs collected in the most heavily polluted sites, Elliott and Commencement Bays, near the urban centers of Tacoma and Seattle. Species compositions of marine fauna also reflected the pollution levels. Findings of this study show that the marine resources of Puget Sound, perceived as clean by consumers, are highly contaminated by toxic chemicals in some areas. (Cassar-FRC)

THE USE OF STRONTIUM-87/STRONTIUM-86 RATIOS TO MEASURE ATMOSPHERIC TRANSPORT INTO FORESTED WATERSHEDS,
Yale Univ., New Haven, CT. Dept. of Geology and Geophysics.
W. C. Graustein, and R. L. Armstrong.
Science, Vol 219, No 4582, p 289-292, January 21, 1983. 1 Fig, 3 Tab, 12 Ref.

Descriptors: *Strontium, *Nutrients, *Aerosols, Tracers, Fate of pollutants, *Forest watersheds, *Air pollution, Trees, Spruce trees, Aspen trees, Bedrock, Weathering, Deposition, Leaves, *New Mexico, Sangre de Cristo Mountains.

The Sr87/Sr86 ratio was used as a tracer to determine the sources of Sr in natural waters, vegetation, and soils in two small forested watersheds, one covered with aspen and the other with Engelmann spruce and subalpine fir, in the Sangre de Cristo Mountains, New Mexico. This mountain range, 1.6 billion years old, has a higher Sr87/Sr86 ratio than the surrounding, lower terrain, 0.6 billion years old, from which atmospheric Sr aerosols and dust are deposited on vegetation. Dust input from remote areas provided 75% of the Sr in the aspen vegetation; 80% in the spruce vegetation. The remainder of the Sr is derived from weathering of bedrock. The conifers intercepted most of the Sr-bearing aerosol in the watershed; very little was trapped by the deciduous foliage. Sr and nutrients are cycled continuously through a system consisting of upper soil horizons, forest litter, and vegetation. (Cassar-FRC)

AN EVALUATION OF SELECTED HALOCARBONS AND TRACE GASES FOR POTENTIAL USE AS INDICATORS OF GROUNDWATER MOVEMENT AND SOURCE (AND CONTAMINANT MOVEMENT IN THE VADOSE ZONE),
Arizona Univ., Tucson. Dept. of Hydrology and Water Resources.
D. K. Kreamer.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-117266, Price codes: A03 in paper copy, A01 in microfiche. Arizona Water Resources Research Center Completion Report, March 1983. 26 p, 7 Fig, 2 Tab, 4 Ref. OWRT A-111-ARIZ(1), 14-34-0001-1103.

Descriptors: *Tracers, Tracking techniques, *Indicators, Path of pollutants, Pollutants, Water pollution, *Groundwater movement, *Groundwater pollution, Vadose zone, Halocarbons.

Selected trace gases were evaluated as indicators of groundwater movement and source. Measurable quantities of trichloroethylene (TCE), perchloroethylene (PCE), 1,1,1-trichloroethane (TCA), chloroform (CCl sub 3 H), trichlorofluoromethane (F-11), methylene chloride (CH sub 2 Cl sub 2), carbon tetrachloride (CCl sub 4), and other trace gases were found in the gaseous component of the vadose zone. A technique was developed to use these compounds in the gas phase as indicators of groundwater pollution and contaminant migration. TCE was found in concentrations of 0.7 and 8.5 mu g/l respectively for the Phoenix well 35 and Salt River Project well 23.6E-6N, at respective depths of 9.3 and 17.8 feet below ground surface, (approximately 200 and 70 feet above the saturated zone). Halocarbons were measured in the atmosphere above ground, in the gaseous phase at depths of 10, 20, 50, and 90 feet below land surface, and in the groundwater at the Carranza well, Tucson, Arizona. TCE, CCl sub 4, PCE, and CCl sub 3 H showed gradients that increased in concentration toward the water table, indicating a local subsurface of water table source. F-11, TCA, and CH sub 2 Cl sub 2 showed decreasing concentration with depth indicating a possible atmospheric origin. Distribution coefficients between water and gaseous phases were found to be higher in field conditions as compared to laboratory conditions for F-11, CHCl sub 3, CCl sub 4, and PCE, and lower for TCE and CH sub 2 Cl sub 2.

TRACE METAL CONTAMINATION OF SHALLOW MARINE SEDIMENTS NEAR A LEAD SMELTER, SPENCER GULF, SOUTH AUSTRALIA,
Commonwealth Scientific and Industrial Research Organization, Glen Osmond (Australia). Div. of Fisheries and Oceanography.
T. J. Ward, and P. C. Young.
Australian Journal of Marine and Freshwater Research, Vol 32, No 1, p 45-46, 1981. 3 Fig, 6 Tab, 13 Ref.

Descriptors: *Fate of pollutants, *Water pollution sources, *Heavy metals, *Marine sediments, *Bays, Industrial wastes, Organic carbon, Cadmium, Calcium, Copper, Minerals, Magnesium, Manganese, Nickel, Lead, Zinc, Silt.

The surface (< 10 cm) marine sediments of Spencer Gulf, a hypersaline seagrassed embayment, near Port Pirie, South Australia, were examined for concentrations of calcium, cadmium, copper, magnesium, manganese, nickel, lead, zinc, total organic carbon, clay, silt, sand, shell, and 'undissolved fraction' (resistant plant debris). Elevated concentrations of lead, copper, zinc, manganese and cadmium were found in sediments adjacent to the liquid effluent discharge from a lead smelter. Outside the immediate discharge area the concentrations of copper and manganese rapidly approached background levels where their concentrations were correlated to those of noncontaminant sediment parameters. The highest concentrations of cadmium were found further from the source of effluent than those of the other four contaminant metals (copper, manganese, lead, zinc), and decreased to undetectable levels at the furthest site. Lead and zinc also occurred at background concentrations at sites away from the effluent discharge, but no correlations were found between these two metals and other sediment parameters. At sites away from the immediate discharge area no interaction was detected between contaminant metals, sediment parameters, and presence or type of seagrass meadow. (Author's abstract)
W84-00312

MUTAGENICITY OF POTENTIAL EFFLUENTS FROM AN EXPERIMENTAL LOW BTU COAL GASIFIER,
Lovelace Biomedical and Environmental Research Inst., Albuquerque, NM. Inhalation Toxicology Research Inst.
J. M. Benson, C. E. Mitchell, R. E. Royer, C. R. Clark, and R. L. Carpenter.
Archives of Environmental Contamination and Toxicology, Vol 11, No 5, p 547-551, 1982. 1 Fig, 5 Tab, 17 Ref.

Descriptors: *Coal gasification, *Mutagenicity, *Industrial wastes, Public health, Design criteria, Organic compounds, Salmonella strain TA98, Salmonella.

Mutagenicity of potential waste effluents produced by an experimental low Btu coal gasifier was studied in Salmonella strain TA98. Samples studied included producer bottom ash and cyclone dust with little associated organic matter, tars, and water containing organic compounds condensed from the process stream. The organic compounds present in potential waste effluents, except for bottom ash, were mutagenic in Salmonella strain TA98. Except in the case of LH-20 fractions from tar-trap tar, metabolic activation was required for a mutagenic effect. These results indicate that potential gasifier effluents contain compounds which, following metabolism, become frameshift mutagens; others may also be formed. Results of chemical fractionation studies indicate that neutral and polar polycyclic aromatics contributed to the mutagenicity, although in the case of tar-trap tar, other classes of compounds also contributed to the biological activity. Potential health hazards associated with these findings should be considered in the design of future coal gasification facilities. (Baker-FRC)
W84-00317

HEAVY METAL ABSORPTION BY WINTER WHEAT FOLLOWING TERMINATION OF CROPLAND SLUDGE APPLICATIONS,
California Univ., Riverside. Dept. of Agriculture.
A. C. Chang, A. L. Page, and F. T. Bingham.
Journal of Environmental Quality, Vol 11, No 4, p 705-708, October-December, 1982. 7 Tab, 17 Ref.

Descriptors: *Metals, *Sludge disposal, *Sand application, Wheat, Cadmium, Zinc, Heavy metals, Land disposal, Fate of pollutants.

Municipal sludge was applied to a test plot near Rio Vista, California, from 1973 through 1976, at the rate of 33, 66, 107, and 147 tons per ha. Total inputs of heavy metals at the highest application rate (kg per ha) were: Cd, 6.24; Cu, 86.2; Ni, 20.6; Pb, 148.2; and Zn, 567.0. Soils and winter wheat crops were sampled in 1979 and 1980. Grain yields from the land treated with 147 tons per ha of sludge were significantly higher than from control plots. Metals contents (micrograms per g) were: wheat straw--Cd, 0.07-0.16; Zn, 19-26; wheat grain--Cd, 0.04-0.09; Zn, 22-45. These values were slightly higher than in controls but were well within the range typical for wheat grown on uncontaminated soils. Levels of Cu, Ni, and Pb were not elevated in the plant tissue. Added metals were confined almost entirely to the 0 to 15 cm soil layer, in which they were incorporated by plowing. Cd appeared to have a greater tendency to migrate than the other metals. Acidity, electrical conductivity, and water-extractable Cd and Zn levels of the soil were not changed by the sludge treatments. (Cassar-FRC)

OPTIONS FOR HANDLING STILLAGE WASTE FROM SUGAR-BASED FUELS ETHANOL PRODUCTION,
East-West Environment and Policy Inst., Honolulu, HI.
I. P. Willington, and G. G. Marten.
Resources and Conservation, Vol 8, No 2, p 111-129, 1982. 1 Fig, 3 Tab, 9 Ref.

Descriptors: *Industrial waste, *Waste disposal, *Fuel, Stillage processing wastes, Ethanol production, Water pollution sources, Sugars, Hawaii.

Stillage waste from ethanol fuel production can be a serious source of water pollution but it can also be a valuable resource from which to recover useful products such as fertilizer, animal feed, or methane gas. Various possibilities for stillage handling include discharge to adjacent waterway or land area, marine outfall, return to agricultural fields, conventional sewage treatment, lagoon treatment, anaerobic digestion with methane production, incineration to ash for subsequent use as fertilizer, and evaporation to an animal feed. These options vary enormously in their environmental characteristics and the degree to which they are commercially proven, consume or produce energy, lead to useful by-products and cost or generate money. The cost depends on the wastewater characteristics, applicable ambient and emission standards, energy requirements of the distillery, economics, availability and cost of land, and the location of the distillery relative to receiving waters and byproduct markets. The environmental impacts of alcohol stillage upon water quality and the aquatic ecosystem include depletion of dissolved oxygen, discoloration, odors, eutrophication, salinization, acidification, increases in water temperature, changes in species composition of aquatic flora and fauna, and fish kills in extreme cases. The formation of a clearing-house for stillage processing information is proposed to offer assistance to those in need of making the many decisions regarding proper disposal of stillage waste products. (Baker-FRC)

ACCUMULATION OF HEAVY METALS IN UNICELLULAR ALGAE,
Monash Univ., Clayton (Australia). Dept. of Chemical Engineering.
D. Khummongkol, G. S. Canterford, and C. Fryer.
Biotechnology and Bioengineering, Vol 24, No 12, p 2643-2660, December, 1982. 9 Fig, 2 Tab, 33 Ref.

Descriptors: *Accumulation, *Heavy metals, *Model studies, *Fate of pollutants, Algae, Microorganisms, Bioaccumulation, Adsorption, Metals, Phosphates, Cadmium.

A model for metal uptake by microorganisms based on surface adsorption was formulated and applied to cadmium (Cd) uptake by Chlorella vulgaris. When cell growth is modeled, an initial rapid uptake and a subsequent slow uptake is predicted due to the simultaneous effects of growth and surface adsorption. Experimental results in a batch system confirm the rapid initial uptake of metals within a few seconds. This equilibrium is affected by phosphate concentration; the amount of CD adsorbed on the cell decreases as the phosphate level increases. Long-term uptake experiments in growing cultures show a greater metal accumulation than predicted by the adsorption model suggesting the involvement in the slow long-term uptake of some mechanism other than adsorption. A model which incorporates a description of adsorption and of intracellular accumulation is needed to provide a more complete description of metal uptake by microorganisms. (Geiger-FRC)

BIOAVAILABILITY OF PHOSPHORUS INPUTS TO LAKES,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
W. C. Sonzogni, S. C. Chapra, D. E. Armstrong, and T. J. Logan.
Journal of Environmental Quality, Vol 11, No 4, p 555-563, October-December, 1982. 2 Fig, 2 Tab, 16 Ref.

Descriptors: *Phosphorus, *Eutrophication, *Lakes, Phosphates, Water pollution sources, Fate of pollutants, Reviews, Algae, Sediment, Adsorption, Desorption, Water quality management, Agricultural runoff, Suspended sediments, Pollutant identification.

Current information on the bioavailability of forms of phosphorus delivered to lakes from different sources is reviewed with attention to management implications. Dissolved P is readily available for use by algae and higher plants, either directly (inorganic P) or readily convertile (condensed P and organic P). Particulate P is partially available for biological use in the inorganic form (nonapatite inorganic P) and convertile to dissolved reactive P in the organic and condensed forms. Inorganic P in the apatite inorganic form is essentially unavailable. Methods of analyzing for bioavailable inorganic P are described. Potentially available P corresponds with the dissolved reactive P (DRP) plus the fraction of particulate inorganic P obtained by extraction with 0.1 N NaOH. Natural factors influencing bioavailability include the rate of P release from suspended particles, the rate of settling of suspended particles, the equilibrium concentration of DRP, algal uptake, and phosphate desorption rates. Potential bioavailability has been estimated at 20-80% of total P input, usually in the lower part of the range. P sources include agricultural and urban runoff, water and wind erosion, fertilizers, atmospheric deposition, and wastewater effluents. Management programs for lakes should consider bioavailability of P to avoid costly overcontrol of P inputs. Most efficient P management should attack the sources highest in DRP: municipal point discharges and excessive fertilizer application. (Cassar-FRC)

EVALUATION OF NITROGEN AND IRRIGATION MANAGEMENT FOR CORN PRODUCTION USING WATER HIGH IN NITRATE,
Nebraska Univ.-Lincoln. Dept. of Agricultural Engineering.
D. L. Martin, D. G. Watts, L. N. Mielke, K. D. Frank, and D. E. Eisenhauer.
Soil Science Society of America Journal, Vol 46, No 5, p 1056-1062, September/October, 1982. 8 Fig, 1 Tab, 8 Ref.

Descriptors: *Nitrogen, *Crop yield, *Groundwater pollution, *Irrigation, Nitrates, Fertilizers, Corn, Groundwater management, Nitrogen uptake.

The interaction of N and water management for corn production was studied using a field-calibrated computer model. The study was conducted on sandy soils in the central Platte Valley of Nebraska. Nitrogen uptake was strongly influenced by the amount of fertilizer N and irrigation water applied and to a lesser extent by the nitrate-nitrogen concentration of the irrigation water. There was also a strong interaction of these parameters in determining N uptake. The uptake efficiency of fertilizer N was very sensitive to excess irrigation and only slightly affected by the amount of fertilizer applied or the nitrate-nitrogen concentration of the irrigation water. The uptake efficiency of groundwater N was strongly affected by the amount of irrigation water applied and the nitrate-nitrogen concentration of the water, while the amount of fertilizer applied had a lesser effect. Groundwater uptake efficiencies in general were higher and more stable than fertilizer uptake efficiencies. Excess irrigation increased N uptake from groundwater sources under certain conditions. The groundwater N contribution to uptake was large for irrigation water containing more than 10 ppm nitrate-nitrogen and was primarily determined by the amount of irrigation and the nitrate-nitrogen concentration. For 25 ppm nitrate-nitrogen irrigation water and small fertilizer applications more N was extracted from the groundwater through irrigation than was lost due to leaching. (Baker-FRC)

5C. Effects Of Pollution

FEASIBILITY AND EFFECTS OF WATER QUALITY ON BAIT-FISH CULTURE IN AERATED SEWAGE TREATMENT LAGOONS IN VERMONT,
Vermont Univ., Burlington.
G. W. LaBar.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110790, Price codes: A02 in paper copy, A01 in microfiche. Vermont Water Resources Research Center Completion Report, September 1983. 11 p, 1 Tab, 14 Ref. OWRT A-044-VT(1).

Descriptors: Wastewater, *Aquaculture, Water quality, *Lagoons, *Vermont, Sewage treatment, *Shiners.

Golden shiners (Notemegonus chrysoleucas) were successfully cultured in 1 m super 3 floating cages in the final lagoon of an aerated lagoon-type sewage treatment facility in Milton, Vermont. The mortality rate at densities of 50 and 100/m super 3 was 6% and 8% respectively, and at 200/m super 3 was 34% over a two-month period. Zinc concentration increased from 2.0 to 6.6 ppm during the same period, while cadmium, lead, and chromium concentrations did not change significantly.

CELLULAR BIOASSAY OF FISH AS A SENSITIVE INDEX OF WATER QUALITY RELATED TO ASH FROM COAL COMBUSTION,
West Virginia Univ., Morgantown. Water Research Inst.
D. E. Hinton, E. R. Walker, and D. M. Kontir.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110824, Price codes: A05 in paper copy, A01 in microfiche. Completion Report, 1983. 78 p, 12 Fig, 9 Tab, 53 Ref. OWRT A-045-WV(1), 14-34-0001-2152.

Descriptors: *Acid mine water, Analysis, *Analytical techniques, *Bituminous coal, *Cytological studies, Fish, *Fly ash, Methodology, Trace elements, Water Quality, Burning, Chemical Analysis, Electric powerplants, Energy, Evaluation, Metals, Water pollution, *Bioassay, *Trout.

Static exposure of aqueous suspensions of ash from coal combustion to Oryzias latipes (embryo), Pimephales promelas, and Salmo gairdoeri (adults) was done to determine whether cells of gill, gut, and/or lateral-line system could phagocytose particulates. Energy dispersive X-ray microanalysis of specific cells in gill did not reveal presence of particulates after exposure. Studies on intestine and lateral line are continuing. Effects of uptake of one coal associated polynuclear aromatic, 3-methylcholanthrene (3-MC), were studied in trout liver by a coupled structure/function approach. 3-MC caused induction of liver microsomal benzo(a)pyrene (BP) hydroxylasse activity but did not affect epoxide hydrase activity. In-vitro microsomal metabolism of BP was qualitatively and quantitatively altered by prior 3-MC exposure. No morphologic alternations accompanied biochemical changes. Field studies to assess effects of coal combustion byproducts on feral fish tissues and enzymes are continuing.

Descriptors: *Acid mine drainage, *Aquatic habitats, *Benthos, *Chemical properties, *Data interpretation, *Instream flow, *Plankton, Streamflow, Water quality, *Water quality standards, Acid streams, Acidic water, Aquatic life, Assessments, Benthic fauna, Benthic flora, Ecology, Ecosystems, Mine drainage, *West Virginia, Pennsylvania.

Eight homogenous river segments were identified, through cluster analysis, in the upper Monogahela River Basin viz, Cheat Lake, Tygart Lake, an acid drainage segment of the middle Cheat, the lower Monongahela (to Pt. Marion, PA), the upper Monongahela, the upper Cheat, the lower Blackwater River, and the Westfork River (south to Clarksburg, WV). Regression analyses of data from within these segments indicated that instream flow was highly associated with Total Algal Biomass in several of the segments. Regression analyses also showed that instream flow had very little association with the Algal Genera Distribution. The segmental approach to determine these algal associations with instream flow was an extremely effective approach, since considerably more variation in Total Algal Biomass could be explained using the segmental approach as compared with the use of all of the variable data. Five variables showed a general positive association with general instream flow in the basin viz, calcium, conductivity, hardness, magnesium, and dissolved oxygen. Consistent temporal changes in water quality occurred throughout the upper Monongahela River basin within the three sub-basins viz, the Monongahela, the Tygart Valley, and the Cheat Rivers, some fourteen variables showed consistently increasing trends and 14 showed consistently decreasing trends.

Descriptors: *Oil shale, *Leachate, *Cadmium, *Alfalfa, *Chelation, Environmental effects, Crop production, Stream microcosms, Aufwuchs, Invertebrates, Substrates, Benthic environment, Benthic fauna, Nitrification, Utah, Colorado, Water pollution effects.

The goal of this study was to identify potential effects should oil shale leachates in Utah and Colorado reach hardwater stream ecosystems or irrigate agricultural lands. The experimental work focused on interactions between raw oil shale leachate and heavy metals in concentrations naturally occurring in these streams and how these interactions affect the toxicity and bioaccumulation of metals. For the studies on hardwater streams, eight identical stream microcosms were constructed and allowed to establish self-sustaining communities of aufwuchs and invertebrates on natural river substrates. Pairs of streams were exposed to treatments of 20 ug Cd/1 representing the most severe likely concentration in the natural streams), 20 ug Cd/1 plus leachate from crushed raw oil shale, and crushed raw oil shale leachate alone. The other two streams were controls. After three weeks, sampling was conducted to determine changes in community structure and observe biological cadmium accumulation. Clorophyll ratios, aufwuchs biomass, invertebrate density, and invertebrate drift showed no measureable effects. However, cadmium accumulations were recorded in aufwuchs, macro-phytes, invertebrates grazers, particulate feeders, predators, and stream sediments but not affected by the oil shale leachate. Cadmium accumulations by aufwuchs are largely associated with cellular surfaces. Effects of oil shale leachate on cadmium toxicity and accumulation in crops were studied using alfalfa and radish plants with the same four treatments. The plants accumulated up to 4.0 ug/g dry weight cadmium, and slightly higher cadmium accumulations occurred with oil shale leachate. None of the treatments affected crop productivity.

THE INDUCTION OF TOLERANCE TO HEAVY METALS IN NATURAL AND LABORATORY POPULATIONS OF FISH,
Kentucky Water Resources Research Inst., Lexington.
W. J. Birge, W. H. Benson, and J. A. Black.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111756, Price codes: A03 in paper copy, A01 in microfiche. Research Report No 141, June, 1983. 31 p, 1 Fig, 8 Tab, 29 Ref. OWRT A-087-KY(1), 14-34-0001-2119(FY82).

Descriptors: *Cadmium, *Copper, Embryos, Larvae, Water quality, Zinc, *Heavy metals, Water pollution effects, Acclimation, *Toxicity tests, *Bioaccumulation, Fathead minnow, Tolerance.

Aquatic toxicity studies were performed on two natural populations of fathead minnows. One group of organisms was taken from a metal-contaminated flyash pond associated with a coal-fired power plant and the other group was collected from relatively uncontaminated hatchery ponds. Acute tests indicated that flyash pond fish were significantly more tolerant to cadmium and copper than were hatchery fish. As an exposed concentration of 6.0 mg Cd/L in moderately hard water, the median period of survival for flyash pond fish was 50.0 hr compared to 6.8 hr for hatchery fish. Both groups of organisms were about equally sensitive to zinc. The metal-induced tolerance observed with animals from the flyash pond was not a sustained response. Additional studies were undertaken to observe the response of laboratory populations of fathead minnows to acutely toxic cadmium concentrations following acclimation to sublethal exposures of this metal. Based on 96-hr LC sub 50 values, those animals which had recieved 35-days prior exposure to 10 and 50 ug CD/L were 63 to 68% more tolerant to cadmium than were previously unexposed organisms. As with the natural population, tolerance to cadmium in the laboratory fish was not retained. After organisms which had been acclimated to 1o ug Cd/L were transfered to clean water, tolerance to cadmium decreased by three and one-half fold after only 7 days. Developing embryos of the fathead minnow and rainbow trout also acquired tolerance to cadmium. After eggs of the trout had been exposed to 0, 5, and 50 ug Cd/L for 24 days, subsequent acute toxicity tests gave 7-day LC sub 50 values of .7, 1, 59, and 2.02 ug Cd/L, respectively.

RECOVERY PATTERNS IN STREAM COMMUNITIES IMPACTED BY THE MT. ST. HELENS ERUPTION,
Oregon State Univ., Corvallis. Dept. of Fisheries and Wildlife.
P. Wilzbach, T. L. Dudley, and J. D. Hall.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111798, Price codes: A03 in paper copy, A01 in microfiche. Water Resources Research Institute Publication WRRI-83, Oregon State Univ., Corvallis, August 1983. 33 p, 6 Fig, 6 Tab, 11 Ref, 2 Append. OWRT A-059-ORE(1), 14-34-0001-2139.

Descriptors: *Stream recovery, *Stream habitats, *Habitat recovery, *Stream biological communities, Stream biota, Stream fisheries, Aquatic habitats, *Aquatic habitat recovery, Benthic communities, Sedimentation, Channel erosion, Channel scour, Channel morphology, *Mt. St. Helens, *Washington.

Recovery patterns of benthic communities in seven small streams impacted to varying degrees by the eruption of Mt. St. Helens were examined in winter 1981-82, particularly in relation to habitat constraints. Overall abundance and diversity of the communities were low, and instability of channel banks appears to severely limit re-establishment of biota. Communities appear to be undergoing cycles of establishment and denudation in concert with changes in landscape geomorphology. Disturbance events of varying frequencies were also simulated in experimental stream channels to more closely evaluate the response of benthic communities to periodic, non-catastrophic disturbances and to compare this with the response observed to catastrophic perturbation associated with volcanic eruption. Results of simulations suggest that non-catastrophic disturbances may not play a major role in determining stream community over ecological time because the predictability of these events may have enabled evolution in species of adaptive responses to cope with disturbance. Catastrophes appear to have different consequences on stream communities from other disturbances and should be distinguished from them.

THE EFFECTS OF AGRICULTURAL RUNOFF UPON NATURAL WETLAND ECOSYSTEMS,
Concordia Coll., Moorhead, MN. Dept. of Biology.
G. L. Vanamburg.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111905, Price codes: A03 in paper copy, A01 in microfiche. Water Resources Research Center Completion Report, Univ. of Minnesota, St. Paul, September 1983. 40 p, 15 Fig, 8 Tab, 22 Ref. OWRT A-044-MINN(1), 14-34-0001-2125.

Descriptors: *Wetlands, *Agricultural Runoff, *Fertilizers, Nutrients, Productivity, *Minnesota, *Marshes, Ammonia, Nitrogen, Ecosystems.

The purpose of the study was to examine the functioning of the major wetland ecosystem compartments. Two prairie glacial marshes in western Minnesota were studied. The major compartments studied were: (1) watershed soils, (2) watershed runoff, (3) emergent macrophytes, (4) submergent plants, (5) wetland sediment, and (6) wetland waters. Ammonia and nitrate forms of nitrogen contributed significantly to nitrogen entering the wetlands via runoff. Above ground biomass of Typha peaked in mid July ranging from 650 to 988 g/m super 2. Below ground biomass reached a maximum in June, declined until late summer, then recovered to values recorded in early spring. Nitrogen concentrations in Typha shoots increased in early spring then declined throughout the season. Nitrogen concentration of the rhizomes and roots was less than in the shoots, except late in the season. Nitrogen content declined in the rhizomes and roots until mid July, after which N-concentration increased in the rhizomes. Changes in Phosphoros concentration in the shoots, rhizomes and roots were very similar in pattern to nitrogen. Total non-structural carbohydrate concentration in rhizomes and roots declined until mid July, then began increasing. One wetland was dominated by Potamogeton pectinatus, which reached a peak standing crop biomass of 264 g/m super 2 on August 10. The other wetland had Ceratophyllum demersum and P. berchtoldii as co-dominant species. P. berchtoldii reached a maximum standing crop of 128 g/m super 2 on June 30, while C. demersum peaked at 127 g/m super 2 on July 28.

ACCUMULATION OF CADMIUM IN A FRESHWATER FOOD CHAIN EXPERIMENTAL MODEL,
Metz Univ. (France). Toxicology Lab.
J. F. Ferard, J. M. Jouany, R. Truhaut, and P. Vasseur.
Ecotoxicology and Environmental Safety, Vol 7, No 1, p 43-52, 1983. 8 Fig, 4 Tab, 11 Ref.

Descriptors: *Biological magnification, *Bioaccumulation, *Water pollution effects, Fish, *Daphnia, *Chlorella, *Food chains, Crustaceans, Heavy metals, Cadmium, Metals, Algae, Trophic level.

The study of food chain contamination in the laboratory or in nature requires the precise definition of certain terms. An elaborated version of a freshwater food chain model was applied to assess the hazards of cadmium in the aquatic environment. Chlorella algae were exposed to various levels of cadmium for 10 days in Erlenmeyer flasks and were then fed to the second trophic level of Daphnia magna for 20 days. Leucaspius delineatus comprised the third trophic level of fish, which were allowed to feed on the daphnids for 4 days. Toxicity of cadmium to daphnids was measured in terms of mortality, reproduction and total body levels of the heavy metal. Total cadmium levels were also recorded for algae and fish tissues. Results showed a high direct bioaccumulation of cadmium in algae and an indirect bioaccumulation of the same order of magnitude in daphnids. Although the indirect bioaccumulation of cadmium in fish was much smaller, the transfer of the metal from daphnids to fish was obvious. (Geiger-FRC)

THE SIGNIFICANCE OF THE ACCUMULATION OF CADMIUM BY AQUATIC ORGANISMS,
Imperial Chemical Industries Ltd., Brixham (England). Brixham Lab.
D. Taylor.
Ecotoxicology and Environmental Safety, Vol 7, No 1, p 33-42, 1983. 2 Fig, 63 Ref.

Descriptors: *Water pollution effects, *Bioaccumulation, *Cadmium, *Literature review, Crustaceans, Biological magnification, Heavy metals, Metals, Reviews, Mollusks, Gastropods, Aquatic animals.

Cadmium appears on many lists of substances dangerous to aquatic life by virtue of its toxicity at low levels, its persistence and its ability to bioaccumulate. A review of forty laboratory studies on cadmium bioconcentration suggests that the bioaccumulation potential of this heavy metal appears to

have been somewhat exaggerated. Median concentration factors for both marine and freshwater organisms are 100 times; for vertebrate species including fish, concentration factors are 20 times. Bioaccumulation of cadmium by aquatic animals is affected by the speciation of the metal in the aquatic environment, certain abiotic factors such as temperature, salinity, and water hardness, the route of entry of cadmium into the animal, and the action of synergistic and antagonistic substances. There is no evidence in the literature for the biomagnification of cadmium, and the bioconcentration of the metal is only likely to be of significance in a restricted range of gastropod mollusks and some crustacea. TOXICOLOGICAL EFFECTS OF DEHYDROABIETIC ACID (DHAA) ON THE TROUT, SALMO GAIRDNERI RICHARDSON, IN FRESH WATER,
Helsinki Univ. (Finland). Dept. of Zoology.
A. Oikari, B. E. Lonn, M. Castren, T. Nakari, and B. Snickars-Nickinmaa.
Water Research, Vol 17, No 1, p 81-89, January, 1983. 5 Tab, 41 Ref.

Descriptors: *Water pollution effects, *Fish, *Toxicity, *Dehydroabietic acid, Industrial wastes, Effluents, Pulp and Paper industry.

Toxicological and physiological effects of dehydroabietic acid (DHAA), a major poison to fish in pulp and paper mill effluents, were studied by two experiments using rainbow trout, Salmo gairdneri Richardson. In the first experiment fish were acutely exposed for 4 days to an average DHAA concentration of 1.2 mg/liter. In the second the fish were exposed for 30 days to an average of 20 micrograms DHAA per liter. Compared to the controls, fish of experiment 1 displayed a decreased relative weight of liver, increased blood hematocrit, increased hemoglobin, and increased plasma protein concentrations. The aspartate aminotransferase activity of heart muscle was significantly elevated, as was also the lactate dehydrogenase (LDH) of white muscle tissue. In the blood plasma the proportion of muscle-type LDH activity was simultaneously increased. UDP-glucuronyltransferase activities of liver and kidney were strongly decreased. Results suggest an increased and altered use of body energy reserves, decreased plasma volume and impaired liver function. Fish of experiment II showed an increased relative weight of spleen. In addition, liver and gill LDH shifted towards heart-type. It was concluded that 20 micrograms/liter is close to the minimum effective concentration of DHAA for rainbow trout. (Baker-FRC)

THE PERFORMANCE OF A NEW BIOLOGICAL WATER QUALITY SCORE SYSTEM BASED ON MACROINVERTEBRATES OVER A WIDE RANGE OF UNPOLLUTED RUNNING-WATER SITES,
Freshwater Biological Association, Wareham (England). River Lab.
P. D. Armitage, D. Moss, J. F. Wright, and M. T. Furse.
Water Research, Vol 17, No 3, p 333-347, March, 1983. 5 Fig, 8 Tab, 29 Ref.

Descriptors: *Monitoring, *Invertebrates, *Aquatic habitats, Water pollution effects, Water quality, Biological monitoring working party, Species composition, Rivers, Habitats, Macroinvertebrates, Aquatic populations, Classification indexes, Environmental effects.

The Biological Monitoring Working Party (BMWP) system of assigning scores to aquatic habitats was evaluated using macroinvertebrate population data from 268 sites in 41 British rivers varying widely in physical and chemical features. Water quality in the sites was good or fairly good. The BMWP score system ranges from 1, indicating poor water quality, to 10, indicating excellent water quality. Seasonal variation in scores was relatively small, and samples taken in spring, summer, or autumn should give similar average scores per taxon (ASPT), derived from score divided by total number of scoring taxa. Sample replication had little effect on ASPT. Data on BMWP score and ASPT values for 8 groups of sites derived by multivariate classificatory techniques produced considerable variability in achievable score and ASPT. High BMWP scores were most common in the middle reaches; ASPT scores were usually highest in the upper reaches of upland rivers. Shoreline samples had higher scores than midstream samples. ASPT scores also showed differences between sites with similar BMWP scores but different physical and chemical characteristics. Equations for predicting BMWP scores and ASPT were developed to predict theoretical scores for given physical, chemical, and environmental conditions. These equations explained 65% and 22% of the variance for ASPT and BMWP scores, respectively. (Cassar-FRC)

EXPERIMENTAL ESTIMATE OF THE TOXICITY OF DANUBE WATER FOR DAPHNIA MAGNA STRAUS,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
E. P. Shcherban.
Hydrobiological Journal, Vol 18, No 2, p 81-87, 1982. 1 Fig, 3 Tab, 18 Ref.

Descriptors: *Rivers, *Toxicity, *Turbidity, Pollutant identification, Suspended sediments, Danube River, Daphnia magna, Water quality, Monitoring, Water management, *USSR.

Toxicity of Danube water was studied in both acute and chronic experiments of Daphnia magna Straus. No acute toxicity was observed during the study. When the water was exchanged, death of the crustaceans may have been due to a lack of adaptation to turbid Danube water. During certain periods a sharp increase was noted in toxicity of Danube water, indicating nonuniformity of the influx of toxicants and peaks of pollution. The chronic effect of native Danube water leads to a reduction in the duration of life of the daphnia, a lengthening of their post-embryonal development, and a decrease in the fecundity of daphnia over several generations. The toxicity of Danube water apparently results from the presence of impurities, turbid suspensions, as well as certain toxicants. (Baker-FRC)

Gigiena i Sanitariia, No 8, p 5-8, August, 1980. 5 Ref.

Descriptors: *Marine environment, *Microorganisms, *Bioindicators, *Water pollution, Marine biology, Microbiological studies, Viruses, Epidemiology, Seawater, Water pollution effects, *USSR.

Interactions between biological (microbial) and chemical contaminants in marine waters as well as survival patterns of pathogenic and sanitary indicator microorganisms in these waters were studied. The quantitative relationships established in field studies between indicator microorganisms and isolation rates of pathogens of bacterial and viral origin from marine waters made it possible to determine precisely the permissible levels of indicator microorganisms. Indicator organisms characterize the degree of epidemiologic safety of the waters polluted by industrial and domestic sources. (Author's abstract)

EFFECTS OF OIL ON PHYTOPLANKTON METABOLISM IN NATURAL AND EXPERIMENTAL ESTUARINE PONDS,
Mississippi State Univ., Mississippi State. Dept. of Biological Sciences.
A. A. De la Cruz.
Marine Environmental Research, Vol 7, No 4, p 257-263, 1982. 2 Tab, 16 Ref.

Descriptors: *Phytoplankton, *Oil spills, *Estuaries, Water pollution effects, Aquatic plants, Metabolism, Oil pollution, Oil, *Mississippi, *Marsh ponds, Ocean Springs, St. Louis Bay.

A low level oil spill was simulated in small shallow natural estuarine marsh ponds in Ocean Springs and in experimental impoundments near St. Louis Bay, Mississippi. The oil used in the study was Empire Mix crude oil. It is a low sulfur oil and typifies the type of oil pumped along the US Gulf Coast. A simulated spillage of 1.45 mg per liter of water was made. Within 2 hr after the spill the pond was completely covered by oil. After 5 days the oil on the surface had dissipated but was concentrated along the bank, on the mud and on the marsh plants. On day 1 after the spill the oil concentration was shown by gas chromatographic analysis of pond water to be 33 mg/liter, but this quickly dissipated to about 1.5 mg/liter after 2 weeks. Primary production in the phytoplankton community 2 weeks after the spill occurred revealed a 44 to 65% reduction and 30-50% reduction in respiration. Two months after the spill, primary productivity and respiration in the oiled pond were only 17% and 7% lower, respectively, than in the control pond. In the experimental impoundments at a concentration of 0.2 mg Arabian Empire Mix and Nigerian oil per liter of water in situ radiocarbon uptake by phytoplankton was lower than that of the control pond. One or two months later primary productivity was significantly higher in the Nigerian and Arabian oil ponds than in control and Empire Mix ponds. The changes in plankton metabolism in both natural ponds and impoundments were evaluated on the basis of data simultaneously obtained from adjoining control ponds. (Baker-FRC)

G. Champalbert, and G. Patriti.
Hydrobiologia, Vol 89, No 1, p 17-27, April, 1982. 10 Fig, 1 Tab, 19 Ref.

Descriptors: *Water pollution effects, *Wastewater outfall, *Zooplankton, Municipal wastewater, Population density, Aquatic populations, Marseilles, *France, Mediterranean Sea.

Marseilles, France, discharges domestic wastewater into the Mediterranean Sea. Zooplankton populations have been studied in the polluted area situated near the sewage outlet. Samples were collected along a transect following the course of a float cast off close to the outlet. Three zones, corresponding to decreasing pollution, appeared in the zooplankton populations. In the first zone, which was the most polluted zone and extended for about 500 meters from the outlet, a few tolerant species were abundant, including Acartia clausi, Oithona helgolandica, and Oikopleura sp. In the intermediate zone, which extended for a few kilometers, the densitites of some of the less tolerant species increased, including Paracalanus parvus, Clausocalanus sp., Centropages typicus, Oncaeidae, and Corycaeidae. A third zone, extending for

several kilometers, which may be subject to partial pollution due to residual polluted patches of water, contained tyically neritic populations. (Author's abstract)

THE EFFECTS OF LOW LEVEL TURBIDITY ON FISH AND THEIR HABITAT,
North Carolina State Univ. at Raleigh. Dept. of Zoology.
J. P. Reed, J. M. Miller, D. F. Pence, and B. Schaich.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113646, Price codes: A04 in paper copy, A01 in microfiche. North Carolina Water Resources Research Institute Report No 190, August 1983. 50 p, 8 Fig, 6 Tab, 48 Ref. OWRT B-132-NC(1), 14-34-0001-0237.

Descriptors: *Turbidity, *Fish populations, *Aquatic habitats, Ponds, *Water temperature, Water depth, Dissolved oxygen, *Suspended solids, Suspended sediments, *Light penetration, Aquatic plants, Plant populations, Chara, *Cyanophyta, Submerged plants, Fish food organisms, Productivity, Primary productivity, Chlorophyll A, Epilimnion, Secchi disks, Mathematical models, North Carolina, Raleigh.

The effects of low level turbidity on fish habitat were investigated in a pond near Raleigh, NC. Three levels of turbidity were maintained in polyvinylchloride curtain enclosures with open bottoms each of which enclosed 260-400 m super 2 and had a maximum depth of 2 m. Turbidity levels in the pond routinely ranged from 6 to 50 NTU turbidity units with peaks associated with blue-green algal blooms in excess of 120 NTU. Total suspended solids, TSS, explained 68% of the variability associated with turbidity: a 10 mg/1 increase in TSS increased turbidity 6 NTU units. Turbidity directly affected light penetration. As light penetration decreases, the light energy is transformed into heat over a shorter distance and higher epilimnetic temperatures may result. The magnitude of the temperature change increases as the turbidity increases and/or depth of the epilimnion decreases. For an epilimnion depth of 0.25 m, temperatures in the turbid enclosure (28 NTU) were 2-5C higher than the cleared enclosure (14 NTU). However, at the 'normal' epilimnion depth of 1 m, large increases in turbidity resulted in only small temperature increases. Turbidity also had an effect on submerged macrophytes. A reduction from 12 NTU to 6 NTU enabled them, due to the increased available light, to colonize deeper waters. This increase in plant biomass would result in increased invertebrate prey and therefore higher fish production.

EUTROPHY IN LAKE ACULEO, CHILE,
Chile Univ., Santiago. Dept. of Cell Biology and Genetics
S. S. Cabrera, and V. B. Montecino.
Plant and Soil, Vol 67, No 1-3, p 377-387, 1982. 3 Fig, 7 Tab, 12 Ref.

Descriptors: *Eutrophication, *Lakes, *Productivity, Eutrophic lakes, Lake Aculeo, *Chile, Water pollution effects, Nutrients, Nitrogen, Carbon cycle, Primary productivity, Chlorophyll a, Phytoplankton, Algae.

Nitrogen turnover was studied in Lake Aculeo, near Santiago, Chile, a highly eutrophic body of 7 m maximum depth, 4.4 m mean depth, and 5.8 km length. Concentrations of chlorophyll a varied from 487 mg per cu m at 0.6 m depth in January 1981 to 28.4 mg per cu m at 1.0 m depth in September 1980. Primary productivity fluctuated between 578 + or - 24.8 mg C per cu m per hour on the surface in November 1978 to 3.8 + or - 0.9 mg C per cu m per hour at 2.5 m depth in November 1980. Carbon fixation varied from 157,000 kg C per month in June to 1.34 million kg C per month in December for a yearly total of 6.25 million kg C. Nitrogen turnover, based on a C:N ratio of 6:1, was 1.04 million kg N per year. Nutrients from untreated wastewater and agricultural runoff contribute to the eutrophic condition. (Cassar-FRC)

EFFECTS OF TEMPERATURE AND COLOR COMPONENTS OF WASTEWATER DISCHARGES ON AQUATIC COMMUNITIES,
Westvaco Corp., Covington, VA.
T. G. Botkins, Jr.
Tappi Journal, Vol 66, No 3, p 107-110, March, 1983. 4 Fig, 2 Tab.

Descriptors: *Wastewater disposal, *Water pollution effects, *Pulp and paper industry, Industrial wastes, Aquatic life, Fish, Thermal pollution, Effluents, Bioassays, *Virginia, Jackson River.

A thermal discharge demonstration study was conducted to evaluate the effects of temperature and color components of Westvaco's bleached kraft and semi-chemical pulp and paper mill discharges on aquatic communities in the Jackson River. The study included the development of a longitudinal, time-dependent, thermo-hydraulic model to simulate river flows and temperatures after the dam becomes operational, which is being constructed to reduce the extremes of high and low flow of the Jackson River; an evaluation of the thermal tolerance limits of representative, important species of fish and supportive trophic levels relative to anticipated elevations in river temperatures downstream of the mill; and the execution of temperature/color bioassays to assess the joint effect of these factors on a locally important game fish. It was concluded that the discharge of heat and color by the continued operation of the mill will not cause an imbalance of the indigenous aquatic communities in the Jackson River below the mill. Descriptors: *Drinking water, *Toxicity, *Water quality standards, Water softening, Minerals, Calcium, Trace metals, Public health.

Morbidity rates and the results of medical examinations were analyzed and a questionnaire survey was conducted in an effort to assess the health status of the population of a Far Eastern region of the USSR where the drinking water is the slightly mineralized soft water characteristic of the Far East. This water is low in minerals (50 to 70 milligrams per liter), has a low hardness (0.8 to 2.0 milligrams-equivalent per liter), has low levels of calcium (2 to 15 milligrams per liter) and magnesium (2 to 10 milligrams per liter), and is deficient in fluorine (0.2 to 0.3 milligrams per liter), while containing lead, arsenic, cobalt, silver, and molybdenum ions. It has been determined that the water has selective actions on the gastrointestinal tract, urinary organs, bony tissue, and the cardiovascular system, and that diseases of the endocrine and nervous systems and of sense organs are more prevalent in the region under study than elsewhere in USSR. The results of these studies have been confirmed and supplemented by the results of a toxicologic experiment on white rats. White rats given the same water had a skin with reduced bactericidal activity and showed a tendency to impaired lipid and mineral metabolism and thyroid hyperfunction. These findings may be of value i predicting the health status of a community and i developing remedial and preventive measure They may also serve as criteria in establishin revised hygienic standards for drinking water. Descriptors: *Drinking water, *Copper, *Wate quality standards, Heavy metals, Toxicity, Embry onic growth stage, Public health.

When ingested in drinking water where it i present at the level of the existing maximum allow able concentration, copper has an adverse effect o pregnancy. Embryotoxic effects of copper ar manifested in high embryonal mortality and im pairment of ossification processes. It is suggeste that the metal may have a toxic action on the fetu through the maternal organism. The embryotoxi effects are believed to result from alteration caused by copper in the metabolic processes in se cells and in biotransformation of trace elements i the placenta and fetus. It is recommended that th maximum allowable concentration for copper i drinking water be set at a lower level of 0. milligrams per liter on the basis of these toxicologi cal effects. FACTEURS RESPONSABLES DE LA DISTRIBUTION DES GASTEROPODES DULCICOLES DANS LE FLEUVE SAINT-LAURENT (FACTORS GOVERNING THE DISTRIBUTION OF FRESHWATER GASTROPODS IN THE ST. LAWRENCE),
Quebec Univ., Montreal. Centre de Recherche en Sciences de l'Environnement.
A. Lamarche, P. Legendre, and A. Chodorowski.
Hydrobiologia, Vol 89, No 1, p 61-76, April, 1982. 5 Fig, 5 Tab, 36 Ref.

Descriptors: *Water quality, *Water pollution effects, *Benthos, Snails, Saint Lawrence River, Hydrocarbons, Organic compounds, Prosobranchs, Pulmonates, Vegetation.

Freshwater gastropod samples were taken from the Saint Lawrence River near Montreal. The samples were studied in an attempt to characterize the populations living in the benthos and on the vegetation, and in order to define the effects of deteriorating water quality on the aquatic life. A total of 98 samples were collected simultaneously from benthos and macrophytes; populations were expressed as the log of each species' relative abundance. Clustering, principal coordinates and discriminant analyses were used to describe and characterize differences between samples. Diversity was also computed to show the transformations of population structure due to differences in pollution levels. Benthic populations were dominated by prosobranch snails, while pulmonates characterized the vegetation inhabitants. The number of species decreased in response to increasing pollution levels on both types of substrates. High hydrocarbon levels were related to a decrease in the

diversity of snail populations on the vegetation only. A differential dependence of prosobranchs in the benthos and of epiphytic pulmonates on the aquatic medium explains the predominance of each species of snails on each substrate. Modes of nutrition were significant factors. Sporadic oil spills affected the snail populations living on macrophytes. (Baker-FRC)

5D. Waste Treatment Processes

THE APPLICATION OF KAOLIN FOR CONTROL OF HEAVY METALS IN ANAEROBIC SLUDGE DIGESTION,
Georgia Inst. of Tech., Atlanta. School of Civil Engineering.
W. H. Cross, and P. M. Rossello.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110766, Price codes: A04 in paper copy, A01 in microfiche. Environmental Resources Center Report No ERC 11-83, Georgia Inst. of Technology, Atlanta, August 1983. 43 p, 2 Tab, 16 Fig, 23 Ref. OWRT A-092-GA(1), 14-34-0001-1111.

Descriptors: *Anaerobic digestion, *Heavy metals, *Isotherms, Kaolin, *Kaolinite, *Wastewater treatment, Nickel, Copper, Chromium, Zinc.

Six laboratory-scale anaerobic digesters were used to evaluate the potential of kaolin addition for the control of heavy metal toxicity. Adsorption isotherms were obtained for the kaolin-metal system in solutions of the individual metals, nickel, copper, chromium and zinc and in mixtures of the metals. The adsorption-ion exchange capacity of kaolin for the metals decreased in the order Cr(III) > Cu > Ni > ZN. The performance of digesters containing kaolin only, metals only and kaolin and metals was compared to that of a control to which no metals or kaolin were added. The sludge used was obtained from a local secondary activated sludge sewage treatment plant. Kaolin was fed at a concentration of 1,00 mg/l and the metals content in the feed were increased in every digester and throughout the digesters. The addition of kaolin did not have effect on performance in the non-metals fed digester as compared to the control. However, the presence of kaolin in the metals fed digesters appeared to afford a means of minimizing inhibition by the heavy-metals. The kaolin fed digesters became acclimated to slightly higher concentrations of metals than the non-kaolin fed unit and performed nearly as well as the non-metals fed digesters.

ELECTRODIALYSIS IN THE REGENERATION OF PAPER MILL SPENT LIQUOR,
Indian Inst. of Tech., Bombay. Dept. of Chemical Engineering.
K. Radhamohan, and S. Basu.
Desalination, Vol 33, No 2, p 185-200, May, 1980. 12 Fig, 21 Ref.

Descriptors: Desalination, Desalination processes, Regeneration, Environmental pollution abatement, *Electrodialysis, Product recovery, Electromembrane process, Soda, Lignin, Black liquor.

Experiments have been carried out on the electrodialytic regeneration of soda and lignin from alkaline black liquor with the abatement of environmental pollution for a smaller capacity rice straw-based pulping plant. To predict the performance capability of the system, the hydrodynamic characteristics of a multi-compartment electrodialysis cell have been correlated with the polarizing parameters in three simplified equations. For efficient and economical recovery of soda along with lignin, a two stage electromembrane process, consisting of conventional ED with a -C-N-C-N-C arrangement, followed by an electrogravitational technique is recommended.

BOD REMOVAL EFFICIENCIES IN TWO STABILIZATION LAGOONS IN SERIES IN MALAYSIA,
Engineering-Science, Inc., Arcadia, CA.
R. M. Bradley.
Water Pollution Control, Vol 82, No 1, p 114-122, January, 1983. 5 Fig, 1 Tab, 26 Ref.

Descriptors: *Lagoons, *Wastewater lagoons, *Biological oxygen demand, Wastewater treatment, Stabilization lagoons, Wardieburn, *Malaysia.

Average BOD removal efficiencies in the stabilization lagoon system in Wardieburn, Malaysia, averaged 79% from 1975 to 1980; suspended solids removal efficiencies averaged 50%. This two-lagoon system, about 1 ha in total area and 1.4 m operating depth, was designed to serve 8000 people. The BOD effluent standard of 50 mg per liter as attained in all but one year. BOD removal in the primary lagoon was 62-70%; in the secondary lagoon, 26-49%. Fluctuations in suspended solids removal, 26-52% in the primary lagoon and 1-31% in the secondary lagoon, were attributed to algal growth. Algal biomass contributed about 11% of the BOD in the primary lagoon effluent and 50-60% of the BOD in the secondary effluent. This lagoon was classified as facultative for most of the time. Although the surface aerobic layer is thin on occasion, the lagoon is not anaerobic. However, the current BOD loading on the primary lagoon is approaching the maximum level recommended for a facultative lagoon at 29C. Equations are given for calculating a real BOD removal from the primary lagoon, secondary lagoon, and the two lagoons in series. Maximum BOD removal efficiency can be achieved by having a larger surface area on the primary lagoon than on the secondary lagoon, thus maximizing the BOD load on each lagoon. (Cassar-FRC)

MEASUREMENT OF THE PERFORMANCE OF SEWERAGE SYSTEMS AND ASSOCIATED HYDRAULIC STRUCTURES--RECENT DEVELOPMENTS,
Severn-Trent Water Authority (England). Avon Div.
A. J. Baughen, and A. R. Eadon.
Water Pollution Control, Vol 82, No 1, p 77-86, January, 1983.

Descriptors: *Sewer systems, *Flow measurement, *Performance evaluation, Monitoring, Gages, Measuring instruments, *Wastewater treatment.

Monitoring devices for sewage systems are described. Flow measurement is possible with hydraulic devices (flumes, notches, and weirs), chemical dilution tests, velocity and depth measurements, and electromagnetic gages. Sewage level can be measured by many types of gages, ultrasonic gages being especially in favor. Pumping rates may be monitored by calculation from hours run and the design curves, magnetic flowmeters, ultrasonic gages, and Doppler meters. It is also important to monitor ancillary information such as river levels, water table levels, and soil moisture deficit. Instrumentation in use at the Avon Division, Severn-Trent Water Authority, is described. Doppler meters, Arkon bubblers, ultrasonic gages, fiberglass flumes, the Manning Dipper, and level recorders are examples. Future developments include 6-channel recorders, rolling barrel information storage, and computer storage of information. (Cassar-FRC)

THE USE OF PERFORMANCE INDICATORS IN SEWAGE TREATMENT APPRAISAL,
Yorkshire Water Authority (England). Southern Div.
H. B. Tench.
Water Pollution Control, Vol 82, No 1, p 61-76, January, 1983. 7 Fig, 8 Tab.

Descriptors: *Performance evaluation, *Costs, *Wastewater treatment, Yorkshire Water Authority, Operating costs, *England.

The Yorkshire Water Authority developed performance indicators for use in its wastewater treatment plants. These are divided into resource utilization indicators (financial costs, physical parameters, trade effluent, and comparison of population costs), intended to provide information on the cost structures, and works performance indicators (COD removal, etc.), to give information on the standard of service supplied. An evaluation for three areas in the Southern Division of the Yorkshire Water Authority showed that from 1978-79 to 1979-80 operating costs rose by 39% while inflation for resources used rose by 47%. Use of indicators clearly reflected the Rother area's commissioning of a new works, the relatively high operating costs of filter pressing and incineration of sludge combined with a decrease in volume of trade effluent in the Don area, and the low operating costs at Dearne, which uses percolating filters and disposal of liquid sludge to land. (Cassar-FRC)

SOLVING A DIFFICULT SEWER REHABILITATION PROBLEM,
Park Ridge City Engineer's Office, IL.
J. H. Utz.
Public Works, Vol 114, No 3, p 59-60, March, 1983.

Descriptors: *Sewer systems, *Liners, *Rehabilitation, Pipes, Excavation, Environmental effects, *Illinois, Park Ridge.

A badly deteriorated sewer, 21 inches in diameter and 371 ft long, was located under 5 large, healthy elm trees in a residential section of Park Ridge, Illinois. To avoid damage to the trees by conventional excavation, the sewer was rehabilitated with a polyester felt liner impregnated with a liquid thermosetting resin. The liner was installed with an inversion tube and water pressure, which turned the liner inside out and forced it into the pipe. When the liner was in place, the water was heated and recirculated to harden the resin. Installation and curing of the liner took 15 hours. Service to all affected individual homes was restored within 36 hours of starting the installation. Although some excavation was necessary to repair two small sections of sewer and to connect-disconnect some of the service lines, trees and paving were not greatly disturbed. (Cassar-FRC)

TREATMENT PLANT HAS PARK-LIKE SETTING,
Burgess and Niple Ltd., Columbus, OH.
P. M. Shepard, Jr.
Public Works, Vol 114, No 3, p 75-76, March, 1983.

Descriptors: *Parks, *Aesthetics, *Landscaping, Wastewater treatment facilities, Delaware County, *Ohio, Olentangy Environmental Center.

The Olentangy Environmental Control Center, as the new Delaware County, Ohio, wastewater treatment plant is called, was designed to masquerade as a park to avoid detracting from the Highbanks Metro Park across the river. The planners

took special care to minimize noise and odor. The plant contains lawns, extensive landscaping, buildings with cedar siding and shaked roofs, pergola-covered walkways, gazebos, ponds, a split rail fence, and a 30 ft fountain. Aeration tanks, aerobic digesters, and clarifiers are below ground level. About $1.5 million was spent for the esthetic improvements. (Cassar-FRC)

LAND APPLICATION: A NEW APPROACH TO PLANT EFFLUENT TREATMENT,
Law Engineering Testing Co., Marietta, GA.
G. L. Taylor, L. A. Neal, and N. Dee.
Pulp and Paper, Vol 57, No 3, p 81-84, March, 1983. 3 Fig, 9 Ref.

Descriptors: *Pulp and paper industry, *Land application, *Industrial wastewater, Pulp wastes, *Wastewater treatment, Wastewater irrigation, Irrigation, Color removal, Spray irrigation, Lagoons, Wastewater lagoons.

Land treatment of pulp and paper mill effluents is an alternative to traditional methods of waste treatment. Among the advantages of land treatment are elimination of the need for locating new mills on rivers and reduction of waste discharge into rivers. Effluents currently being treated in this manner are sulfite, kraft, groundwood, strawboard, hardboard and insulation, boxboard and paperboard, deinking, and recycling plant types. Four major techniques of waste application, which may also be combined to fit a particular site, are rapid infiltration in a series of shallow lagoons, overland flow (usually down a 2-4% slope), spray irrigation (the most versatile), and soil incorporation (shallow injection or plowing of wastes into soil). Calculation of the assimilative capacity of a site is difficult and depends on many factors, including the soil and groundwater properties. Land treatment is particularly effective for reducing color in effluents. Lignin, which is responsible for most of the color in pulp mill effluents, is readily degraded by soil microbes. (Cassar-FRC)

A PILOT-SCALE PERCOLATING FILTER FOR USE IN SEWAGE TREATMENT STUDIES,
Trinity Coll., Dublin (Ireland).
N. F. Gray, and M. A. Learner.
Water Research, Vol 17, No 3, p 249-253, March, 1983. 5 Fig, 14 Ref.

Descriptors: *Pilot plants, *Filters, *Wastewater treatment plants, Sampling, Monitoring, Percolating filters.

A pilot-scale percolating filter, easily constructed from materials available in a storeroom or at a sewage works site, is described. It consists of three stacked reinforced concrete manhole sections supported on a concrete block-reinforced concrete base. The medium is supported on a steel grid resting inside the concrete blocks. Sampling and monitoring facilities are built in. This apparatus is easily modified, versatile, low in cost, and adaptable to a wide range of research, evaluation, and development work. (Cassar-FRC)

SIMULTANEOUS ELECTROFLOTATION AND DISINFECTION OF SEWAGE (ELECTROFLOTTATION ET DESINFECTION SIMULTANEE D'EAUX RESIDUAIRES URBAINES),
Electricite de France, Chatou. Direction des Etudes et Recherches.
P. Costaz, J. Miquel, and M. Reinbold.
Water Research, Vol 17, No 3, p 255-262, March, 1983. 9 Fig, 5 Tab, 9 Ref.

Descriptors: *Disinfection, *Oxidation, *Chlorination, Flotation, Electroflotation, *Wastewater treatment, Wastewater oxidation, Flocculation, Activated sludge process.

Simultaneous electroflotation and disinfection of wastewater was studied on the pilot-plant scale. Chlorine and oxygen were generated from chloride ion, the amount depending on current density (100, 200, and 300 A per sq m), COD, chloride concentration (300 to 3000 mg per liter), and oxidation potential of the effluent. Effluent had been pretreated with ferric chloride and an organic polymer. Solid-liquid separation was improved compared to that achieved by static clarification for 2 hours, and the disinfection efficiency was equal to or better than that obtained with gaseous chlorine. For example, at a 900 mg per liter chloride concentration and the three current densities tested, a quantity of 47 million coliforms per 100 ml in the effluent was reduced to 0-1400 per 100 ml. The process produced highly concentrated sludges, suitable for recycling in the activated sludge process. (Cassar-FRC)

EFFECT OF TEMPERATURE AND PH VALUE ON THE GROWTH-RATE CONSTANTS OF NITRIFYING BACTERIA IN THE ACTIVATED SLUDGE PROCESS,
Water Research Centre, Stevenage (England).
H. A. Painter, and J. E. Loveless.
Water Research, Vol 17, No 3, p 237-248, March, 1983. 5 Fig, 6 Tab, 14 Ref.

Descriptors: *Nitrification, *Activated sludge process, *Kinetics, Bacteria, *Wastewater treatment, Temperature effects, Hydrogen ion concentration, Growth rates.

The specific growth rates of nitrifying bacteria were determined under nonequilibrium conditions in a laboratory-scale activated sludge plant at three temperatures (16, 20, and 25C) and over a pH range of 6.0 to 8.5. Generally, nitrification began soon after the beginning of the experiment. However, no nitrification occurred at pH 6.0. For most experiments a pH range of 7.5-8.0 was optimum, with a gradual decrease in rate constant on each side of optimum. There was no apparent pattern in the effects of temperature on nitrification. Undiluted and stale sewage produced higher doubling times than dilute sewage. The reason for this was probably a lower concentration of toxic, inhibitory substances in the dilute sewage. The onset of nitrification was more positive with diluted sewage than with stale or undiluted sewage. Addition of ammonium carbonate lowered doubling times slightly. Growth rate constants at 20C, pH 7.5, were 0.10-0.42 per day for Nitrosomonas in activated sludge grown on domestic sewage. In about half the cases the rate constant for Nitrosomonas was greater than that for Nitrobacter. (Cassar-FRC)

HOW THE ROCKY MOUNTAIN ARSENAL IS HANDLING GROUNDWATER CONTAMINATION,
Rubel and Hager, Inc., Tucson, AZ.
D. B. Hager, and C. G. Loven.
Water/Engineering and Management, Vol 130, No 3, p 18-19, March, 1983. 1 Tab.

Descriptors: *Groundwater pollution, *Chemical wastes, *Activated carbon, Adsorption, Rocky Mountain Arsenal, Denver, *Colorado, Water pollution control, Injection wells, Organic compounds, *Wastewater treatment.

Groundwater contaminated with inorganic and organic chemical wastes from the operations at the Rocky Mountain Arsenal, Colorado, has been contained by slurry wall and hydraulic barriers and by treatment of water with a counter-current granular activated carbon adsorption system. Several dewatering and reinjection wells were installed as part of the activated carbon system. Diisomethylphosphonate was found in highest concentrations, maximum 1130 micrograms per liter. Other chemicals of particular concern were dicyclopentadiene, dibromodichloropropane, and pesticides. Monitoring of treated water quality during 1982 indicated that levels of these chemicals in treated effluents were below detection limits. (Cassar-FRC)

FACTORS INFLUENCING BIOFOULING OF REVERSE OSMOSIS MEMBRANES AT WATER FACTORY 21: CHEMICAL, MICRO BIOLOGICAL AND ULTRASTRUCTURA CHARACTERIZATION OF THE FOULIN LAYER (VOLUME III-B),
Orange County Water District, Fountain Valley CA.
H. F. Ridgway, D. G. Argo, and B. H. Olson.
Available from the National Technical Informatio Service, Springfield, VA 22161 as PB84-11357(Price codes: A06 in paper copy, A01 in microfiche Final Report, November 1981. 113 p, 30 Fig, 1 Tab, 50 Ref. OWRT C-80159-R(5)(8520).

Descriptors: *Advanced wastewater treatment *Wastewater renovation, *Water reuse, Revers osmosis, Microbial fouling, Biofilm composition Fouling bacteria, California, Water Factory 21 Orange County Water District.

Biofouling of cellulose diacetate reverse osmosi (RO) membranes used for dimineralization of mu nicipal wastewater was investigated at Water Fac tory 21, a 0.66 m3/sec (15mgd) advanced wastewater reclamation facility located in Fountain Valley, California. The fouling material was primarily organic in composition (at 90% dry wt, and contained 13% to 18% carbohydrate and 15% to 30% protein. The principal inorganic elements detected were chlorine, calcium, phosphorus and sulfur. Electron microscopy revealed that the fouling bacteria were attached within the biofilm via a network of extracellular polymeric fibrils. Substantial concentrations of adenosine 5'-triphosphate were detected in the biofilm, indicating that the fouling bacteria were metabolically active and potentially able to grow and multiply in situ. In addition, the attached fouling bacteria actively accumulated (3H) glucose and were able to reduce p-iodonitrotetrazolium violet dye (INT) to the insoluble INT-formazan complex. Plate counts indicated 4x10 to the fifth power to 5x10 to the sixth power bacteria per cm squared on the feedwater surface of the RO membranes. Presominant genera associated with the feedwater and permeate water surfaces of the RO membranes were identified. Predominant genera associated with the same or related microbial genera were detected in the feedwater supplying the RO facility. Although there was some correlation between the physico-chemical and microbiological properties of the RO feedwater and the membrane fouling layer, the dynamics of this interaction were not investigated.
W84-00135

EVALUATION OF MEMBRANE PROCESSES AND THEIR ROLE IN WASTEWATER RECLAMATION: VOLUME III-A,
Orange County Water District, Fountain Valley, CA.
D. G. Argo, and M. G. Rigby.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113588, Price codes: A14 in paper copy, A01 in microfiche. Final Report, November 1981. 252 p, 68 Fig, 78 Tab, 12 Ref, 1 Append. OWRT C-80159-R(8520)(4).

Descriptors: *Advanced wastewater treatment, *Wastewater renovation, *Water reuse, Reverse osmosis, Electrodialysis, Ultrafiltration, Biofilm development, Fouling, Costs, *California, Water Factory 21, Orange County Water District.

Water Factory 21 (WF-21) in Orange County, California, is a 15-mdg advanced wastewater treatment (AWT) plant designed to reclaim biologically treated municipal wastewater for injection into a seawater barrier system. Processes included are lime treatment, air stripping, filtration, activated carbon adsorption, reverse osmosis (RO), and chlorination. This report presents operating data from WF-21 collected during the final year of a three-year project. The effectiveness of each treatment process is presented including RO dimineralization, ultrafiltration, and electrodialysis. The data collected show that the combined processes, including RO, used at WF-21 are capable of producing a very high quality water on a reliable basis. Treatment reduced all contaminants, to levels below national interim primary drinking water regulation maximum contaminant levels. It was found that lime clarified secondary effluent can be used

as feedwater to a RO dimineralizer. This lime/RO process substantially reduces the pretreatment requirements and cost of reclamation. Experiments with new low pressure membranes (250 psi) show great potential for reducing RO costs. The major cost of RO flux decline was formation of an active biofilm on the membrane surface. The cost of AWT at WF-21 is $1,140 per million gallons. The cost of RO demineralization is $836 per million gallons. These costs include all operation and maintenance as well as amortization of capital.
W84-00136

ABATEMENT OF HEAVY METALS IN INDUSTRIAL EFFLUENTS BY A CATALYZED, ELECTROCHEMICAL REMOVAL SCHEME,
North Carolina State Univ. at Raleigh. Dept. of Chemical Engineering.
J. L. Ayres, and P. S. Fedkiw.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113638, Price codes: A04 in paper copy, A01 in microfiche. North Carolina Water Resources Research Institute Report No 207, August 1983. 71 p, 12 Fig, 6 Tab, 41 Ref. OWRT A-133-NC(1), 14-34-0001-2135.

Descriptors: Water pollution control, *Heavy metals, Water pollution treatment, Electrochemistry, *Industrial wastewater, *Ion-selective electrodes, *Wastewater treatment, Copper, Lead, Iron, Zinc, Nickel.

This report represents the work performed in the first year of a two-year project. An evaluation of lead and copper deposited on a reticulated vitreous carbon (RVC) surface as a catalytic agent for the electrodeposition of Cu(II), Ni(II), Pb(II), and Zn(II) from dilute solutions (10 mg/1) was performed using a flow-through porous electrode reactor. Copper showed a very strong catalytic activity for Zn(II) and Ni(II) electrodeposition at loadings from 20 to 50 ug/cm super 2. The removal efficiency of Cu(II) from a 100 mg/1 solution circulated from a reservoir to a porous, flow-by, uncatalyzed electrode and back to the reservoir was examined. A current efficiency of 87% was measured as the concentration of Cu(II) was lowered from 95.6 ppm to 0.05 ppm. An electrical operating cost of 11 cents per lb. of copper recovered can be estimated from the results. This should be compared to the cost of chemicals required if precipitation is used of 65.3 cents per lb. of copper removed. In addition, the volume of waste generated is considerably lower in the electrolytic route in comparison to precipitation; the volume of precipitation-generated sludge composed of 4% solids is 4.45 gal per lb. of copper as compared to .0279 gal per lb. copper (50 percent of void volume in RVC filled by copper) electrochemically generated.
W84-00161

ANAEROBIC FLUIDIZED BED EXPERIMENTATION WITH A MOLASSES WASTEWATER,
Aktiebolaget Sorigona, Staffanstorp (Sweden).
B. Frostell.
Process Biochemistry, Vol 17, No 6, p 37-40, November/December, 1982. 2 Fig, 3 Tab, 11 Ref.

Descriptors: *Anaerobic conditions, *Fluidized beds, *Biological wastewater treatment, *Wastewater treatment, Sand, Industrial wastewater.

A beet molasses wastewater from a baker's yeast factory (COD, 9.1 kg per cu m) was treated in a laboratory scale anaerobic fluidized bed using a sand carrier and external solids recycling. After design changes, stable treatment at 20-25 kg COD was attained. At a loading rate of 22.2 kg COD per cu m per day methane conversion was 43%. Maximum biomass concentration was 22 kg VS per cu m, of which only 13 kg VS per cu m was attached. By the end of the 165-day experiment the solids retention time was 11-13 days. The system tolerated high suspended solids concentrations--average, 11.6 and maximum, 14.0 kg MLTSS per cu m. Startup time necessary to achieve a load of 20 kg COD per cu m per day was long, over 3 months. (Cassar-FRC)

THREE COST EFFECTIVE I/I PROGRAMS.
Public Works, Vol 114, No 1, p 56-57, January, 1983.

Descriptors: *Sewer systems, *Rehabilitation, *Sewer infiltration, Leakage, Grouting, Inspection, Costs, Infiltration, New Jersey, West Virginia, Kansas.

Television inspection and chemical grouting helped three cities to substantially reduce sewer system infiltration/inflow (I/I). Hamilton Township, New Jersey, used a relatively inexpensive TV inspection and sealing unit, which eliminated 90-95% of infiltration and dropped the wastewater flow from 12 to 7 mgd. Not only was the proposed emergency expansion of the treatment plant cancelled, but half of the 16.5 mgd plant was shut down. The inspection unit is also used to view newly built sewer lines before acceptance. In Newport News, Virginia, the I/I was 573% of the actual sewage. TV inspection and smoke testing units, joint sealing chemicals, and associated equipment is being used in a four-year in-house rehabilitation program. Wichita, Kansas, has been running a TV-assisted I/I control program for 12 years. It uses a grout pumping system that can handle a variety of grouts. Although no records of actual I/I reduction have been kept, 53,000 leaking joints have been identified and repaired during the last 9 years. (Cassar-FRC)

THE EFFECT OF CHLORINE DIOXIDE SUBSTITUTION ON BLEACHING EFFLUENT TOX!CITY AND MUTAGENICITY,
C-I-L, Inc., Mississauga (Ontario). Chemicals Research Lab.
G. P. Donnini.
Pulp and Paper Canada, Vol 84, No 3, p 74-78, 80, 1983. 4 Fig, 6 Tab, 38 Ref.

Descriptors: *Chlorine dioxide, *Pulp and paper industry, *Bleaching agents, Wastewater effluents, Kraft mills, Pulp wastes, Mills, Toxicity, Daphnia, Chlorination, Mutagenicity, Wastewater treatment.

Kraft pulps were bleached with various levels of chlorine dioxide substitution in the chlorination stage, and the toxicity and/or mutagenicity of the resulting C and El filtrates, as well as of some combined CED and CEDED effluents, were determined. Low levels (4 and 10%) of chlorine dioxide substitution provided significant reductions in the total Daphnia toxicity of C+El filtrates. High levels of substitution provide additional, but proportionally smaller, decreases in toxicity. The mode of chemical addition and the amount of chemicals applied can effect the toxicity substantially . High chlorine dioxide substitution reduces the mutagenicity of chlorination effluents, but sequential chlorination yields higherr activity than simultaneous addition. The toxicity values of combined CED and CEDED effluents from low and high chlorine dioxide substitution are not substantially different. The toxicity values of the respective C and El filtrates do not accurately predict the toxicity of combined effluents. Dl stage filtrates are acutely toxic and could be responsible for a substantial portion of the toxicity of mill acid bleach effluents. In order to compare realistically the toxic load of bleach plant outfall from low and high chlorine dioxide substitution, the toxicity of combined effluents should be measured. (Baker-FRC)

THE APPLICATION OF THIN FILM COMPOSITE MEMBRANES IN PLATE-AND-FRAME SYSTEMS FOR WATER PURIFICATION,
Danske Sukkerfabrikker, Nakskov. Driftteknisk Lab.
W. K. Nielsen, and S. Kristensen.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 383-396, 5 Fig, 3 Tab, 7 Ref. (1st Vol of Proc. of Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Membranes, Water purification, Hyperfiltration, Thin film composite membranes, Plate-and-frame systems, Pulp and paper industry, Food processing industry, Dairy industry, Whey.

Thin film composite membranes are now at such a level where stable and reliable membranes can be produced on a large scale. Utilization of thin film composite membranes within water desalination and in the dairy industry for concentration of whey is outlined. The application for concentrating waste-water streams in the pulp and paper industry is mentioned. The membrane is developed for water desalination. Temperature resistance is 80C for operation. The membrane can stand cleaning with nitric acid, phosphoric acid, caustic soda, and soda ash. Because of a high salt rejection, the rejection of small organic solutes is excellent. This is of importance to waste waters and dairy and food products. Sanitation and cleaning are improved. High temperature operation makes the process possible in new areas and enables capacity increase. Experience is summarized gained with thin film composite membranes in plate-and-frame systems with special regard to: (1) chemical and temperature stability; (2) influence of elevated temperature on organic low molecular weight substances, such as lactic acid and urea; (4) cleaning and sanitation schemes and experience within a number of different applications; and (5) the prospects of thin film composite membranes for water treatment and in the food and dairy industry.

CHEMICAL TREATMENT FOR REUSE OF WASTEWATER EFFLUENTS IN SAUDI ARABIA,
University of Petroleum and Minerals, Dhahran (Saudi Arabia).
H. A. Kharajian, R. H. Siddiqi, and S. Farooq.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 437-438, 1 Tab (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Water reuse, Wastewater renovation, Reverse osmosis, Lime, Sodium hydroxide, *Desalination, *Wastewater treatment, Dhahran, *Saudi Arabia.

Reclamation of municipal wastewater is receiving increasing attention in Saudi Arabia. In the reclamation process desalination of wastewater becomes necessary when total dissolved solids (TDS) concentration is high. At most locations in Saudi Arabia the TDS of wastewaters ranges between 2000 and 4000 mg/l. A considerable fraction of the dissolved solids is due to salts of divalent cations, magnesium and calcium. Chemical precipitation of these salts would therefore be required as either a single step treatment in the reclamation process or as a preparatory treatment in conjunction with reverse osmosis or electrodialysis. The chemical treatment of raw and biologically treated wastewater at Dhahran was investigated. Lime and sodium hydroxide were used. Both were effective in reduction of TDS and hardness. Some typical preliminary results of treatment of secondary effluent are given.
W84-00246

UTILIZATION OF THE WASTE CONCENTRATED SEAWATER IN THE DESALINATION PLANTS,
Asahi Glass Co. Ltd., Chiba (Japan).
T. Kawahara, and K. Suzuki.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 499-507, 8 Figs, 4 Tab, 2 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Manama, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Electrodialysis, Desalination apparatus, Flash evaporator, Salts, Brines, Water reuse, Salt recovery.

Concentration of waste brine exhausted from flash evaporator was studied with a newly developed concentration technique. The results were that concentration of NaCl in concentrated brine, its purity, electric power consumption and its cost,

respectively, were 264(g/l), 96(%) (NaCl/T.salts) and 238(KWH/t-NaCl). Installation cost was 3,380 million yen and total concentrated brine cost including amortization was 2,760 sub 3(Yen/t-NaCl) under the following design basis. Quantity of waste brine 100,000(m super 3/D), production capacity 610,000(t-NaCl/Year), current density 7(A/dm2), electricity 5(Yen/KWH). Installation cost and operating cost for recovery of salt have been substantially reduced, so electrodialytic concentration process appears more attractive than it has hitherto been the case for the industrial use or manufacturing of table salt.

WATER SOFTENING BY DIFFUSION USING CATION EXCHANGE MEMBRANES,
Central Salt and Marine Chemicals Research Inst., Bhavnagar (India).
B. S. Joshi, and K. P. Govindan.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 509-516, 2 Figs, 5Tab, 7 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Manama, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, *Membrane processes, Water treatment, Water softening, Cation-exchange membranes.

Water softening by an interionic diffusion process across a cation-exchange membrane is studied. A twenty compartment laboratory scale unit with an effective cross-sectional area of 63 sq cm is assembled and studied for water softening using an interpolymer cation exchange membrane developed in this institute. Alternate compartments formed by thin gaskets are fed with synthetic hard waters and sodium chloride as regenerant solution in a counter current series flow arrangement. Results on softening of hard water of 500, 1000, 1500 ppm as CaCO3 containing sodium chloride in the ratios: 1:0, 1:1 and 1:2 are given. The regenerant concentrations of 0.5, 1.0 and 1.5 N are studied for softening efficiency. Diffusion of salt and water through the membranes and the effect of regeneration levels to achieve 80% softening is also investigated. The commercial prospects for a continuous softening system by this method are discussed.
W84-00253

DEMINERALIZATION BY ELECTRODIALYSIS USING AMPHOLYTIC ION-CONDUCTING SPACERS,
Central Salt and Marine Chemicals Research Inst., Bhavnagar (India).
K. P. Govindan, and P. K. Narayanan.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 517-527, 1 Fig, 5 Tab, 7 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Manama, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Electrodialysis, Water treatment, Demineralization, Ion-conducting spacers.

The synthesis of ampholytic ion-conducting spacers and their use in demineralization of low saline waters with cost of treatment are given. The various modifications on the use of conducting spacers in demineralization by electrodialysis are discussed. Extension of the technique in prevention of environmental pollution by recovery of valuable materials and elimination of harmful ions in trace quantities is also described.

IS MONOD'S APPROACH ADEQUATE FOR THE MODELING OF PURIFICATION PROCESSES USING BIOLOGICAL TREATMENT. (FAUT-IL ABANDONNER LE FORMALISME DE MONOD POUR LA MODELISATION DES PROCESSUS DE DEPOLLUTION PAR VOIE BIOLOGIQUE.),
Institut National des Sciences Appliquees de Lyon, Villeurbanne (France). Lab. de Chimie et Genie de l'Environnement.
H. Roques, S. Yue, S. Saipanich, and B. Capdeville.
Water Research, Vol 16, No 6, p 839-847, June, 1982. 7 Fig, 1 Tab, 25 Ref.

Descriptors: *Biological treatment, *Wastewater treatment, *Mathematical studies, Mathematical models, Anaerobic treatment, Fermentation.

Experimental evidence has demonstrated that it is not possible to use Monod's model to express the velocity of purification processes using biological treatment. This is so because it is impossible to estimate the effects of the substrate concentration at the inlet on the substrate concentration at the outlet during a continuous fermentation; to obtain, in certain cases, positive values of the maximum growth rate during graphical determinations using the linearized form of the model; or to estimate the variations of the saturation constant as a function of the sludge age and the biomass fraction in each tank in the contact-stabilization process. A new model, which is drawn from Contois' model, is proposed and the equation for this model is presented and discussed. The proposed model is compatible with a limitation of the growth by accumulating inhibiting metabolites in the culture medium. It also keeps the possibility to characterize the limitation of the culture by exhaustion of the substrate and to take into account the substrate transfer resistance surrounding the microorganism. This formulation is shown to generalize the previous modeling processes by presenting Monod's, Contois's, Powell's, and Elmaleh's classical models as particular cases corresponding to particular values of the constants used. The application of this model to different effluents is demonstrated, and numerical values of the constants used are given. (Carroll-FRC)

LAND APPLICATION OF UNTREATED INDUSTRIAL WASTE WATER,
North Carolina State Univ. at Raleigh. Dept. of Soil Science.
L. D. King.
Journal of Environmental Quality, Vol 11, No 4, p 638-644, October-December, 1982. 8 Fig, 3 Tab, 10 Ref.

Descriptors: *Land application, *Wastewater irrigation, *Industrial wastewater, Denitrification, Wastewater disposal, Irrigation, Nitrates, Fate of pollutants, Pulp and paper industry, Heavy metals, Metals, Sodium, Wastewater treatment.

Untreated and treated wastewaters from a fiberboard mill were applied to fescue grass by spray irrigation for 4 years. The wastewaters varied widely in chemical composition over the study period. Initial application rate was 1.4 cm per week. After 2 years the untreated wastewater rate was changed to 1.5, 2.0, and 3.0 cm per week. 20%-30% of applied N was recovered in the harvested crop. Concentrations of Mn, Ni, Pb, and Cr in the unwashed crop were increased slightly, to levels well below the maximum tolerable in forage. Soil nitrate concentrations in untreated wastewater irrigation and control plots were not significantly different, except when the wastewater had very high nitrate levels. By the end of the study total N levels were higher in the 150-210 cm soil level near the surface; highest soil P was 150 ppm (untreated wastewater at highest application rate); highest soil Ca was >4000 ppm (untreated wastewater at 2 cm per week application); highest soil K was 340 ppm (untreated wastewater at highest application rate). Soil Na accumulated in the subsoil 136 ppm. This high concentration was attributed to a Na spill, pointing out the need for an equalization basin in the system. Soil pH was increased by the wastewater treatments to 7.4-7.8. Results showed that extensive pretreatment of wastewater before disposal to land did not significantly improve soil properties as compared with treated wastewater. (Cassar-FRC)

USE OF BIOLOGICAL FILTERS FOR TREATING AGRICULTURAL DRAINAGE EFFLUENTS,
Agricultural Research and Education Center, Sanford, FL.
K. R. Reddy, K. L. Campbell, D. A. Graetz, and K. M. Portier.
Journal of Environmental Quality, Vol 11, No 4, p 591-595, October-December, 1982. 4 Fig, 6 Tab, 19 Ref.

Descriptors: *Nutrient removal, *Aquatic plants, *Agricultural runoff, Wastewater treatment, Nitrates, Phosphates, Ammonium, Nitrogen removal, Phosphorus removal, Macrophytes.

Nutrient removal from agricultural drainage water was studied in a reservoir system containing aquatic macrophytes. The system, located near Lake Apopka, Florida, consisted of three reservoirs in series, each about 1240 cu m in volume, containing water hyacinth in R2, elodea in R3, and cattail in R4. The control reservoir (R5) contained Chara sp. but no macrophytes. Influent water contained 0.2 micrograms nitrate-N per liter, 0.1-1.0 micrograms ammonium-N per liter, 1.5-10.0 micrograms organic N per liter, and up to 2 micrograms per liter total P. Residence times were 3.6 days for R2 alone, 7.2 days for R2-R3, 9.4 days for R2-R3-R4, and 10.9 days for R5, the control. In the R2, R2-R3, R2-R3-R4, and R5 systems, respectively, removals adjusted for seepage losses were: nitrate-N, 81.1%, 91.5%, 92.1%, and 85.0%; ammonium-N, 78.1%, 77.8%, 80.0%, and 62.4%; organic N, 32.0%, 24.0%, 21.7%, and 6.2%; phosphate-P, 54.0%, 71.3%, 84.6%, and 58.5%; and total P, 32.2%, 43.6%, 66.2%, and 6.9%. CONTROLLING COOLING TOWER PH AND CYCLES OF CONCENTRATION,
J. R. Hefler.
Industrial Water Engineering, Vol 19, No 3, p 24-28, May/June, 1982. 7 Fig, 7 Ref.

Descriptors: *Cooling towers, *Acidity, *Water treatment, Temperature effects, Humidity, Water quality, Carbon dioxide, Carbonates.

In open recirculation cooling systems the cooling tower pH must be controlled in response to external changes which are not controllable. These external changes include atmospheric temperature, humidity, and pollution levels, and makeup water quality. The most cost-effective operation can only be assured by precise determination of circulating water pH and its cycle of concentration, the two factors that can be controlled. In the acid addition system of control, stable wide-range acid feed is provided. A metering pump is used as the final control element to deliver acid at a rate independent of changes in viscosity, suction lift, or discharge pressure. The acid addition system should be interlocked with the circulating and makeup pump starters so that no acid is fed unless there is flow in the cooling system and the dilution pump is operating. Cooling water pH control is a means of suppressing carbonate ion and offsetting the loss of free carbon dioxide as the heated water is aerated. In addition to the acid addition system and pH control there are also systems for controlling the flow which regulate makeup to keep pace with evaporation and preset blowdown as a ratio of makeup. Cooling water chemistry is still far from being cut and dried. Considerable help can be obtained if the operation of all well instrumented systems were to be analyzed and compared. There are various technical societies which can be helpful in this regard. (Baker-FRC)

5E. Ultimate Disposal Of Wastes

A CASE STUDY OF DRY WELL RECHARGE,
Arizona Water Resources Research Center, Tucson.
L. G. Wilson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110865, Price codes: A04 in paper copy, A01 in microfiche. Completion Report, September 1983. 55 p, 15 Fig, 13 Tab, 10 Ref. OWRT A-114-ARIZ(1), 14-34-0001-1103.

Descriptors: *Urban runoff, *Waste disposal wells, Water pollution, Vadose water, *Recharge wells, Storm runoff, *Arizona, Tucson.

Five injection tests were conducted on an experimental dry well at a site near Tucson, Arizona. Goals of the tests were to determine (1) intake characteristics of the well, (2) flow patterns in the vadose zone, and (3) attenuation of urban runoff pollutant analogs (metals, microorganisms, and organic matter) in vadose zone/ground-water flow systems. Specific intake rates exceeded specific capacity values at a nearby pumping well. A perched ground-water system and a water table mound were observed by neutron moisture logging with lateral flow velocities averaging 500 ft/day. Metals were detected breaking through in a vadose-zone sampling well. Microbial tracers also arrived at the vadose zone sampling well, but peak values were markedly reduced below input values. The initial concentration of organic matter breaking through in the sampling well was 58% of the input values. No organic matter or microorganisms were detected in pumped ground-water samples. It was generally concluded that (1) dry well injection of urban runoff may develop perched ground water systems capable of spreading injected water within the radius of influence of nearby wells, and (2) given the pollutant loading rates of the test, ground water was not deteriorated in quality.

MAXIMUM APPLICATION RATES FOR LAND TREATMENT OF SEPTAGE,
Minnesota Univ., St. Paul. Dept. of Agricultural Engineering.
C. J. Clanton, R. E. Machmeier, J. L. Anderson, and M. J. Hansel.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111806, Price codes: A03 in paper copy, A01 in microfiche. Water Resources Research Center Completion Report, Univ. of Minnesota, St. Paul, September 1983. 23 p, 8 Fig, 4 Tab, 12 Ref, 1 Append. OWRT A-045-MINN(2).

Descriptors: *Wastewater, *Septage, *Groundwater, *Land treatment, Soils, Nitrates, Phosphorus, Salts, *Application rates, Wastewater disposal.

Two years of data from a three year study indicates septage application rates of 1120 and 1500 kg/ha of nitrogen resulted in increased concentrations of nitrates in soil water extracts for a Hubbard loamy sand, Waukegan silt loam and Lester clay loam. Nitrate movement is quite slow through the Lester clay loam so that negative impacts of high rates of application will not be as great when compared to the silt loam or loamy sand. However, if the objective is to prevent movement of high concentrations of nitrates through the soils these application rates are too high. The application of septage did not affect the concentrations of fecal streptococcus and fecal coliforms in the soil water when comparing the treated plots for both years. This indicates that the soils evaluated have the capability to reduce the high level of fecal organisms found in septage to levels found normally in soil water. Septage application resulted in a significant increase in concentration of soil water calcium, magnesium, sodium and potassium during the first year. In addition, there was no increase in phosphorus concentration in the soil water.

DESIGN OF SEA OUTFALLS - THE LOWER LIMIT CONCEPT OF INITIAL DILUTION,
N. J. Bennett.
Proceedings of the Institution of Civil Engineers. Part 2: Research and Theory, Vol 75, No 1, p 113-131, 1983. 5 Fig, 1 Tab, 7 Ref.

Descriptors: *Outfall sewers, *Path of pollutants, *Mathematical studies, *Dye dispersion, *Wastewater disposal, Outfall, Coastal waters, Water currents, Design criteria, Statistical analysis, Tracers, Fate of pollutants, *England, East Sussex River.

A detailed sequel study was carried out by the East Sussex Water and Drainage Division of the Southern Water Authority. The study measured dye-sewage concentrations at the mouth and sea surface at the Hastings long sea outfall after 333 injections of Rhodamine WT dye within a diffuser port over a 3.5 month period. Ambient current, angle of ambient current relative to the diffuser, salinity, temperature and depth measurements were also recorded. Results of mathematical and statistical analyses of collected data showed that the formula derived by the Water Research Center for use in moving water conditions greatly underestimates dilutions and that the use of correction factors as a basis for measuring dilutions in moving water is not substantiated. A simpler, lower limit formula is proposed for use in sea outfall design which may be applied for the measurement of dilutions under a wide range of conditions. (Geiger-FRC)

RAYONIER PRODUCES ANIMAL FEED FROM SECONDARY SLUDGE AT SULFITE MILL,
J. C. W. Evans.
Pulp and Paper, Vol 57, No 3, p 124-126, March, 1983. 1 Fig.

Descriptors: *Sludge disposal, *Pulp and paper industry, *Dewatering, Industrial wastes, ITT Rayonier, Feeds, Pulp wastes, Sulfite mills, Carver-Greenfield evaporator, Evaporation, Biological wastewater treatment, Activated sludge process, Wastewater treatment, *Washington.

Sludge from the Rayonier Port Angeles, Washington, sulfite market pulp mill is converted into animal feed. This was the most suitable of 13 alternative sludge dewatering and disposal schemes evaluated. Pilot studies showed that the dry product had a protein content of 41-48% and a heat content of 9000 Btu. In the two-stage dewatering operation, the biomass from the secondary treatment plant is conditioned with polymers prior to belt filtration. The filtrate is returned to the secondary treatment plant, and the filter cake is sent to the second stage, a Carver-Greenfield evaporator system. With this process a metered quantity of oil is added to the sludge and the mixture passed through a series of multiple-effect, falling-film evaporators. Solids remain in the oil as a fluid slurry, which is centrifuged to recover the solids. Oil is recycled. This method of sludge disposal has no negative effects on water quality or the environment. (Cassar-FRC)

COMPOSTING OFFERS ALTERNATIVE FOR EFFLUENT PLANT SLUDGE DISPOSAL,
E and A Consultants, Stoughton, MA.
J. E. Alpert, E. Epstein, and C. De Groot.
Pulp and Paper, Vol 56, No 11, p 127-129, November, 1982. 2 Fig, 2 Tab.

Descriptors: *Sludge disposal, *Pulp wastes, *Composting, Industrial wastes, Aeration.

The Beltsville forced aeration sludge composting process is suitable for pulp and paper mill wastes. Raw sludge is mixed with a bulking agent such as bark or wood chips and piled 8 to 9 ft high over a perforated drainage pipe. A blower draws or blows air through the pile to maintain a desired temperature for the 2-6 week composting period. Finished compost can be sold as a soil conditioner or used by the paper mill itself for reforestation projects, odor scrubbing, or as fuel for boilers. Capital and operating costs for a 10 dry ton per day composting plant are $699,062 and $133,369, respectively. (Cassar-FRC)

SIMULATING LAND APPLICATION SITING EFFECTS ON WATERSHED HYDROLOGY,
Agricultural Research Service, Fresno, CA.
J. E. Ayars, M. Yaramanoglu, and H. N. Holtan.
Transactions of the ASAE, Vol 26, No 1, p 100-105, 1983. 5 Fig, 7 Tab, 5 Ref.

Descriptors: *Wastewater disposal, *Spray irrigation, Irrigation practices, Irrigation, *Land disposal, Waste disposal, Water quality, Hydrologic models, Model studies.

A hydrologic model was used to simulate the effects of land application of treated sewage effluent on the hydrologic response of a watershed. The effect of soil type, soil drainage characteristics and geology was tested on the disposal capacity of a land application system. Also, three conditions were used to initiate an irrigation: soil water was reduced to any value less than saturation; to 65% of available water capacity in the profile; and to 35% of available water capacity. Results demonstrated that base flow in a watershed is an important design parameter and that disposal rates needed to be matched to base flow and evapotranspiration potential. It was also shown that perennial cropping and frequent irrigation have the potential to increase disposal capacity. The study also demonstrated that a hydrologic model is a tool which provides a method to evaluate specific effects of a spray irrigation site on watershed hydrology which cannot be done easily in any other way. 5F. Water Treatment and Quality Alteration

THE ECOLOGY OF ACID-FAST ORGANISMS IN WATER SUPPLY, TREATMENT, AND DISTRIBUTION SYSTEMS,
Illinois Inst. of Tech., Chicago. Pritzker Dept. of Environmental Engineering.
C. N. Hass, M. A. Meyer, and M. S. Paller.
Journal of the American Water Works Association, Vol 75, No 3, p 139-144, March, 1983. 9 Tab, 15 Ref.

Descriptors: *Chlorination, *Microorganisms, *Filtration, Bacteria, *Acid-fast organisms, *Water treatment, Water distribution, Fate of pollutants, Turbidity, Manchester, Concord, *New Hampshire.

Acid-fast organisms were well correlated with total coliforms throughout the Manchester and Concord, New Hampshire, water systems. Water from 8 locations in each system, from raw water to consumer, was sampled and analyzed for these organisms plus plate count, membrane standard plate counts, free and total chlorine residual, total organic carbon, pH, turbidity, and temperature. In raw water densities of acid-fast organisms correlated with concentrations of total coliforms and turbidity level. Acid-fast organisms were largely removed by sand filtration and further decreased in density with increasing distance from the treatment

plant. The acid-fast organisms were relatively resistant to chlorination and actually increased by 22% during chlorination at Concord. (Cassar-FRC)
W84-00022

KINETIC MODEL FOR OZONATION OF TOXIC WATER CONTAMINANTS,
Georgia Inst. of Tech., Atlanta. School of Civil Engineering.
E. P. Minchew, F. M. Saunders, and J. P. Gould.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111889, Price codes: A02 in paper copy, A01 in microfiche. Environmental Resources Center Report No ERC 13-83, Georgia Inst. of Technology, Atlanta, September 1983. 16 p, 4 Tab, 7 Fig, 16 Ref. OWRT A-095-GA(1), 14-34-0001-1111.

Descriptors: Contamination, *Decomposition, *Kinetics, *Ozonation, *Ozone, Ozone decomposition, Hydrogenion concentration, Model studies.

A laboratory study was conducted on ozone decomposition kinetics in buffered water at various pH values. Ozone decomposition was shown to be highly dependent on pH, contaminant level, ozone concentration and UV irradiation. At pH values of 1.85 and 6.65, the order of the ozone decomposition was shown to be a function of ozone concentration and ranged from third-to zero-order for concentrations of 10 super -8.4 to 10 super -12 M. Accumulation of ozone-decomposition intermediates was shown to significantly effect the rate of ozone decomposition. The results of the study will aid greatly in evaluation of the oxidation of contaminant organics in waters and wastewaters and in determination of the relative rates of contaminant oxidation and ozone self-decomposition.
W84-00048

CONVENTIONAL WATER TREATMENT PROCESS OPERATES IN UNCONVENTIONAL MANNER,
Quicksall (W.E.) and Associates, Inc., New Philadelphia, OH.
J. S. Bachman, and J. R. Morgan.
Public Works, Vol 114, No 3, p 50-53, March, 1983. 2 Fig, 1 Tab.

Descriptors: *Ion exchange, *Water softening, *Brine disposal, Water treatment, New Philadelphia, *Ohio, Tuscarawas River, Manganese, Iron.

The water treatment plant at New Philadelphia, Ohio, is based on a pressure type sodium cycle ion exchange system, with concurrent removal of iron and manganese by pressure type manganese greensand filters. Waste brine regenerate is discharged into the Tuscarawas River. Design studies showed that at full operating capacity the plant would discharge 16,740 pounds of chloride daily into the receiving stream. This discharge would increase chloride concentrations in the river by 2.5 mg per liter at mean river discharge and by 16 mg per liter at low flow. This additional chloride load was acceptable to the Ohio EPA, since an upstream industry discharge raises chloride levels in the river to 450-900 mg per liter. Normal background levels of chloride are 26-30 mg per liter. The process uses split stream softening. About 80% of the flow is softened; the remaining 20% bypasses the softeners and is only treated for Mn and Fe removal. The brine discharge is spread evenly over a 24-hour period. The annual cost (capital amortization and operation/maintenance) is about half of a conventional lime-soda ash treatment plant (estimated at about $1 million for a 5 mgd plant). (Cassar-FRC)
W84-00120

FACTORS INFLUENCING THE ADSORPTION OF BACTERIA TO MAGNETITE IN WATER AND WASTEWATER,
Queensland Univ., Brisbane (Australia). Dept. of Microbiology.
I. C. MacRae, and S. K. Evans.
Water Research, Vol 17, No 3, p 271-277, March, 1983. 5 Fig, 6 Tab, 15 Ref.

Descriptors: *Bacteria, *Adsorption, *Magnetite, Water treatment, Sirofloc process, Wastewater treatment, Calcium, Magnesium, Hardness, Polyelectrolytes.

The interaction of bacteria and magnetite in the Sirofloc water treatment process was investigated. Magnetite particles pretreated with 8 cycles of alternating magnetization and demagnetization were not significantly more effective in removing 5 types of common bacteria than untreated magnetite. At low bacterial levels (10 million CFU per ml) the magnetite concentrations from 0.5-4% produced similar bacterial removals. At higher bacterial levels (665 micrograms per ml dry weight) 1-2% magnetite was required to remove 95% of the cells. Adsorption of bacteria was essentially complete within 10 min. with 1% magnetite in the presence of 11.13 mg per liter Ca and 9.62 mg per liter Mg adsorption of bacteria was 97-99% in the pH range 2.5-10.0. In the absence of Ca and Mg adsorption was 97-99% in the pH range 3-6 and 50% at pH 10. Addition of 0.5% Catoleum 8101 polyelectrolyte improved bacterial adsorption at magnetite concentrations of 0.05% and 0.10% but not at 0.25% and 1%. Bacterial removal from a wastewater effluent (hardness, 180 mg per liter as CaC03) was 70% in the first cycle and 98.1% in the second cycle. In the presence of Ca and Mg desorption of bacteria was very small: E. coli, 0.02%; Streptococus fecalis, 0.33%; Pseudomonas stutzeri, 6.28%. Without Ca and Mg 39.05% of E. coli were desorbed. THE STABILITY IN WATER OF A NEW CHLORAMINE DISINFECTANT,
Auburn Univ., AL. Dept. of Chemistry.
S. D. Worley, W. B. Wheatley, H. H. Kohl, J. A. Van Hoose, and H. D. Burkett.
Water Resources Bulletin, Vol 19, No 1, p 97-100, February, 1983. 2 Fig, 14 Ref.

Descriptors: *Disinfectants, *Water treatment, *Bacteria, Purification, Stability, *Chloramines, 3-chloro-4,4-dimethyl-2-oxazolidinone, Chlorine.

The stability in water of a novel new chloramine agent, 3-chloro-4,4-dimethyl-2-oxazolidinone (I), has been compared to the stabilities of several other water disinfectants. Agent I proved to be remarkably stable in water solution and in dry storage. It also far exceeds all other agents tested in this work in this respect. Agent I could be termed as a slow release disinfectant which kills bacteria upon demand. Furthermore, its great stability and low percent dissociation to hypochlorous acid should prevent the formation of toxic trihalomethanes in treatment plants. The stability of agent I is certainly a desirable attribute which renders it of potential use as a disinfectant for small water supplies, swimming pools, cooling water for power plants, and possibly even for municipal treatment plants. Agents tested in this research included N-chlorosuccinimide, 2,4-dichloro-5,5-dimethylhydantoin, trichloroisocyanuric acid, calcium hypochlorite, commercial grade HTH, and household bleach. The total chlorine content of a water solution of agent I in a demand free environment remained constant over a period of at least 8 weeks. (Baker-FRC)

Gas- und Wasserfach: Wasser/Abwasser, Vol 123, No 4, p 190-194, April, 1982. 4 Fig, 3 Tab, 43 Ref.

Descriptors: *Water treatment, *Oxidation, *Disinfection, *Ultraviolet, Hydrogen peroxide, Water analysis, Water quality, Organic compounds, *Organochlorine compounds, Agricultural chemicals, Hexachlorocyclohexane, Hexachlorobenzene, Heptachlor, Aldrin, Polychlorinated biphenyls, Dichlorobenzenes.

A study was made of the reduction of gamma-hexachlorocyclohexane (gamma-BHC), hexachlorobenzene (HCB), heptachlor, aldrin, polychlorinated biphenyl (2-PCB) and two dichlorobenzenes in water by UV-irradiation and simultaneous hydrogen peroxide addition. The study was designed to evaluate the UV/hydrogen peroxide method of disinfection and oxidation for water treatment. The reduction of these compounds under various hydrogen peroxide concentrations and water flux rates was measured. Reductions between 0 and 89% of the organochlorine compounds added were obtained. The reliability of the method was examined by error analysis, which gave an overall error for the method as a whole of 18.8%. Problems in the use of UV/hydrogen peroxide and capabilities of the method for purpose of water treatment include possible mutagenicity of hydrogen peroxide and its reaction products as well as the potential for formation of toxic intermediate degradation products. Gigiena i Sanitariia, No 8, p 8-10, August, 1980. 2 Tab, 7 Ref.

Descriptors: *Membranes, *Ultrafiltration, *Polysulfonamide, Toxicity, Laboratory studies, Filtration, Membrane processes, *Water treatment, *USSR.

New polysulfonamide ultrafiltration membranes of the 'Vladipor' type were evaluated under conditions simulating their actual use in water treatment. The membranes performed satisfactorily and did not affect the physical or chemical properties of the water. Permanganate oxidizability and brominated substance contents were similar for membrane-filtered and control water samples. Little or no alteration of biochemical parameters was seen in rats supplied with membrane-filtered drinking water for 6 months. Thus, the membranes are recommended for use in water purification facilities for domestic and industrial water supply systems. (Author's abstract)

WATER SUPPLY IN DEVELOPING COUNTRIES: IMPROVING ON CURRENT PRACTICE,
A. D. Barrett, and M. B. Pescod.
Journal of the Institution of Water Engineers and Scientists, Vol 36, No 5, p 323-342, September, 1982. 4 Fig, 4 Tab, 24 Ref.

Descriptors: *Water supply, *Developing countries, *Planning, Design criteria, Urban water supply, Rural water supply, Water supply development, Management.

A critical review is offered of current practices in water supply in developing countries. The needs of developing countries for urban and rural water supply will only be met if adequate funds are made available during the United Nations International Water Supply and Sanitation Decade and if improvements are made in current practice, both in planning and implementation, including training, operation and maintenance. Design criteria and

standards are reviewed in terms of the quality of drinking water, quantity of drinking water to be provided, population to be supplied, and the proportion of standpipes to house connections. Urban and rural water supply is considered, using source selection and development techniques, water treatment, and water distribution. The subject of technology transfer contains reviews of local level education, on the job training, research and development and the role of international agencies. Water supply master plans and feasibility studies include demand forecasts, staging and time factors, cost considerations and engineering studies along with specialist studies, and project appraisals. Descriptors: *Nitrogen compounds, Chemical reactions, Water treatment, Chlorine, Ozone, Ozonation, Activated carbon, Carcinogens, Nitrosamines.

This study found that N-nitrosamines (NA) are highly stable compounds. The most effective methods for eliminating them from water were found to be ozonation and the use of activated charcoal filters. The NA transformation products that were formed under the action of chlorine and ozone are not as toxic as, and accumulate less than, the N-nitrosamines. NA chlorination products have a blastomogenic action, the mechanism of which appears to differ from that of the NA itself. (Author's abstract)

WATER TREATMENT FOR INDUSTRIAL BOILER SYSTEMS,
C. R. Peters.
Industrial Water Engineering, Vol 17, No 6, p 16, 18-26, November/December, 1980. 9 Fig, 1 Tab, 7 Ref.

Descriptors: *Boiler water, *Corrosion control, *Chemical precipitation, Water treatment, Phosphates, Amines, Steam, Heat transfer, Chelation.

The objectives of boiler water treatment are satisfactory steam purity, minimum corrosion, and minimum deposition. A variety of treatments are available to fit the needs of the many types of boiler systems, ranging from simple, natural circulation to high pressure systems with complex flow patterns and multiple components. Antifoam treatments can reduce carryover and improve steam purity. Examples are given for calculating the carryover and amounts of contaminants present in the steam. Deposits, which retard heat transfer, may be controlled by chemical additions to prevent formation of precipitates or to form precipitates easily removed by blowdown. Corrosion control must be tailored to individual boiler systems. Possible treatments include conventional phosphate treatment (maintenance of phosphate and hydroxide residual), coordinate phosphate treatment (trisodium phosphate residual with no free sodium hydroxide), congruent phosphate treatment (prevention of sodium hydroxide formation under hideout conditions), all volatile treatment (ammonia or hydrazine), chelants (ethylenediamine tetraacetic acid and/or nitrilotriacetic acid), and condensate/feedwater system treatment (hydrazine, neutralizing amines, or filming amines). A table lists guidelines for water quality for boiler feedwater and boiler water for pressures up to 2000 psig. (Cassar-FRC)

Water Research, Vol 16, No 10, p 1437-1450, October, 1982. 10 Fig, 7 Tab, 17 Ref.

Descriptors: *Chlorination, *Organic compounds, *Chlorinated hydrocarbons, Water treatment, Chloroform, Trihalomethanes, Ammonia, Phenols, Aromatic compounds, Aliphatic compounds.

Formation of chlorinated organic compounds, especially trihalomethanes, during chlorination of surface water was studied by chlorinating a number of organic compounds at concentrations of 0.000001 to 0.00001 mole in neutral medium. The aliphatic compounds, including acids, aldehydes, and alcohols, were relatively inert to chlorination. On the other hand, chlorine demands of 5-12 moles of chlorine per mole of organic precursor were obtained with aromatic compounds of the phenol and aniline types. Many organic compounds produced chloroform at molar yields of $<5\%$. Metapolyhydroxybenzenes and metachlorophenols were especially good precursors of trihalomethanes. Kinetic constants of chloroform formation are given for acetone, acetylacetone, resorcinol, phloroglucinol, and 3,5-dichlorophenol. Although chlorine demands of some compounds were very high, the chloroform produced accounted for only a small proportion. Chlorination of resorcinol produced large proportions of trichloroacetic acid (molar yield $<10\%$) and monochloromaleic acid (molar yield 60%). Chlorination of 3,5-dichlorophenol produced tetrahalogenated and pentahalogenated three-carbon compounds. Chloroform was also produced in significant amounts during chlorination of highly reactive precursors in the presence of ammonia or amine compounds. (Cassar-FRC)

NEW APPROACH TO COOLING WATER TREATMENT PROVIDES INCREASED PLANT PROFITABILITY,
E. W. Ekis, Jr.
Industrial Water Engineering, Vol 19, No 4, p 10, 12-15, 1982. 5 Fig.

Descriptors: *Cooling water, *Corrosion control, Water treatment, Nalco Delta-T System, Delta-T System, Biocides, Training, Process control, Industrial water.

The Nalco DELTA-T approach is designed to enhance plant profitability by optimizing cooling water treatment systems. The concept includes problem solving, program selection, program management, problem anticipation, and special services. Safety and efficiency of adding liquid biocides were improved by the Bioductor feed system, based on the Venturi principle. Hydrocarbon leaks into the cooling water system, difficult to detect and responsible for up to thousands of dollars per day in damages, are located with the aid of a specially designed sample collection device. The samples are extracted with Freon and analyzed by a portable spectrophotometer. In choosing a suitable treatment system four basic corrosion control approaches are in use: chromate/zinc, alkaline zinc, all organic, and stabilized phosphate. Choice of a program depends on the individual situation, whether pH upsets, elevated temperatures, iron contamination, or inorganic phosphate contamination are present. Operator training programs are available to improve treatment systems management. The Delta-T program anticipates problems and has plans for dealing with them. For example, an accidental acid overload may be promptly handled by using an iron dispersant to limit fouling during the critical period. The program also has special services, such as an on-line method for removing iron-based deposits from cooling systems without shutting down plant production. (Cassar-FRC)

TREATMENT TECHNIQUES FOR REMOVING ORGANIC COMPOUNDS FROM GROUND WATER SUPPLIES,
Pirnie (Malcolm), Inc., Paramus, NJ.
J. E. Dyksen.
Industrial Water Engineering, Vol 19, No 4, p 16-21, 1982. 3 Fig, 1 Tab, 7 Ref.

Descriptors: *Organic compounds, *Activated carbon, *Aeration, Water treatment, Adsorption, Groundwater, Solvents, Chlorinated hydrocarbons.

Aeration and granular activated carbon adsorption are the most practical and effective treatment methods for removing volatile organic compounds from groundwaters. Some groundwater supplies contain significant concentrations of solvents, trichloroethylene and tetrachloroethylene being found most frequently. Aeration equipment is classified into two categories: diffused aerators, where bubbles are passed upwards through the water, and waterfall aerators, such as cascades, multiple trays, spray nozzles, and packed columns. Well-designed packed columns can remove volatile organics with efficiencies $>$ 99%. Efficiency depends on several factors, especially the Henry's Law constant. Granular activated carbon is the best available broad spectrum system for removing volatile organics, but effectiveness of adsorption is uneven. Of the solvents usually found in groundwater, higher molecular weight compounds and unsaturated compounds are adsorbed better than lower molecular weight compounds and saturated compounds. Adsorption isotherms are not sufficient to design a system. Pilot tests are necessary to account for the competitive adsorption among the solvents present. Off-site regeneration of spent carbon is usually more economical than on-site regeneration. (Cassar-FRC)

RECOGNITION OF PIPE LEAKS BY SHORT TERM MEASUREMENTS (ERKENNUNG VON ROHRLEITUNGSLECKS DURCH KURZZEITMESSUNGEN),
F. G. Heide.
Gas- und Wasserfach: Wasser/Abwasser, Vol 123, No 4, p 181-183, April, 1982. 2 Fig, 1 Tab, 9 Ref.

Descriptors: *Water distribution, *Leakage, *Drinking water, Water conveyance, Measurement techniques, Measuring instruments, Flow measurement.

Many water utilities conduct routine leakage surveys at regular intervals of a few years to identify sources of leaks and to reduce leakage in drinking water distribution systems. New methods, such as leakage analysis, and new instruments, such as the leak noise correlator, have been successfully applied in an effort to improve the efficiency of the search for leaks. However, using these methods, leaks are only detected at the time such surveys are conducted. A new, permanent leakage control method has been developed which uses measuring stations which perform regular, automatic, short duration measurements of the night flow at 24-hour intervals to allow determination of when and where the search for leaks should start. 5G. Water Quality Control

A TEST OF THE WATER AND LAND RESOURCE ANALYSIS SYSTEM IN THE NEW JERSEY PINE BARRENS,
Cornell Univ., Ithaca, NY. Center for Environmental Research.
S. Pacenka, and K. S. Porter.

Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111848, Price codes: A04 in paper copy, A01 in microfiche. Completion Report, October 1983. 56 p, 20 Fig, 3 Tab, 2 Append. OWRT A-100-NY(1), 14-34-0001-2134.

Descriptors: *Technology transfer, Hydrologic budget, *Groundwater pollution, *Nitrogen cycle, *New Jersey, *Mathematical models, Groundwater recharge, Hydrologic cycle, Pine Barrens.

Technical tools to help determine how best to protect ground-water recharge from contamination are not widely available. This report summarizes an effort to apply an evolving set of such tools, the Water and Land Resource Analysis System (WALRAS), in the New Jersey Pine Barrens. The WALRAS was originally developed by Cornell University to aid ground-water management on Long Island, New York. The Pine Barrens have similar soils and climate to Long Island, making the transfer hydrologically feasible. The areas also share concerns over nitrate contamination of ground water. The project cooperators, Cornell University, Rutgers University, and the New Jersey Pinelands Commission, focused their efforts on a pilot study area near Hammonton, New Jersey. During the course of the project, a number of technical manuals about the WALRAS were developed, its component computer programs were improved, and a data base was assembled for the pilot study area. The transfer experience pointed out the need for computer access early in such a model-based project. It also illuminated the need for personnel skilled in multidisciplinary data interpretation and mathematical model application. The New Jersey team's companion report describes the results of the pilot area test.

A LINEAR PROGRAMMING ECONOMIC ANALYSIS OF LAKE QUALITY IMPROVEMENTS USING PHOSPHORUS BUFFER CURVES,
Economic Research Service, Washington, DC.
C. W. Ogg, H. B. Pionke, and R. E. Heimlich.
Water Resources Research, Vol 19, No 1, p 21-31, February, 1983. 6 Fig, 5 Tab, 27 Ref.

Descriptors: *Phosphorus, *Lake restoration, *Nonpoint pollution sources, Model studies, Greenlane Reservoir, *Pennsylvania, Economic feasibility, Cultivation, Erosion control, Water quality control, Eutrophied lakes, Soil erosion, Agricultural watersheds, Watershed management.

The economic feasibility of reducing phosphorus loads from agricultural land to a water supply reservoir was investigated using a linear programming model, which combines economic and physical modeling. Phosphorus loss coefficients were estimated using the Universal Soil Loss Equation for runoff and soil erosion and phosphorus buffer curves for labile P. The curves relate soil and solution P concentrations, assuming chemical equilibrium. The buffer curve approach using labile P instead of the traditional total P has several advantages, including the fact that labile P is more closely related to algal growth, soil P fertility, and crop productivity than total P. The model was applied to Greenlane Reservoir, the most severely eutrophied water body in Pennsylvania. The target total P level was established at 65 micrograms per liter, far less than the present 262 micrograms per liter, of which 60% comes from point sources and 40% from nonpoint sources. The model produced a variety of crop and conservation practices for four combinations of point-nonpoint labile P control. Some suggested changes were wider use of contour and no-till, shifting more acreage to hay production, and growing alfalfa on the steeper slopes. (Cassar-FRC)

INVESTIGATIONS OF STRATEGIES FOR REDUCING AGRICULTURAL NONPOINT SOURCES IN THE CHOWAN RIVER BASIN,
North Carolina State Univ. at Raleigh. Dept. of Biological and Agricultural Engineering.
F. J. Humenik, B. A. Young, and F. A. Koehler.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113562, Price codes: A09 in paper copy, A01 in microfiche. North Carolina Water Resources Research Institute Completion Report, September 1983. 172 p, 8 Fig, 29 Tab, 21 Ref, 6 Append. OWRT A-110-NC(1), 14-34-0001-1135.

Descriptors: *Nonpoint pollution sources, Agricultural runoff, *Agricultural watersheds, Erosion control, Nitrogen, Phosphorous, Biological samples, Soil absorption capability, *Management practices, *Chowan River Basin, Stream discharge data, Water quality data, Watershed soils.

A three-year study was conducted in the Chowan River Basin to measure water quality changes resulting from implementation of best management practices (BMP's) to reduce agricultural nonpoint sources. Important components of the overall study framework were to conduct surveys for assessing agricultural practices and producer attitudes associated with the development and evaluation of an agricultural nonpoint source control program and to conduct a supportive publicity, educational and technical assistance program. A cooperatively executed field sampling program resulted in over 13,000 actual USGS flow values, and 876 concentration samples. Predictive models were developed to fill data gaps and allow calculation of annual yields. The total complement of data obtained in this study emphasized the need of employing the total systems approach in conducting and evaluating nonpoint source control programs on a watershed basis. Important components of this total systems approach are recommendations to control agricultural nonpoint sources and methods for evaluating water quality changes. Study results lead to a better definition and documentation of the advantages and limitations of monitoring to determine actual land loading coefficients and to evaluate specific relationships between BMP's installed, and resulting water quality changes on a watershed basis.

SANITARY HYDROBIOLOGY AND HYDROPARASITOLOGY. GENERAL PRINCIPLES OF POLLUTION PROTECTION OF LAKE WATERS,
Limnologicheskii Inst., Irkutsk (USSR).
G. I. Galeziy.
Hydrobiological Journal, Vol 18, No 2, p 48-51, 1982. 5 Ref.

Descriptors: *Water quality control, *Lakes, Water pollution sources, Water quality, Benthos, Plant life, Physical properties, Microorganisms, *USSR, Lake Baikal.

Lake Baikal, an extremely pure water lake, was monitored for the slightest changes in the water, and the entire ecologic system of the adjacent region was also studied to try to develop strategies and tactics for the protection of other lakes which unavoidably experience the effect of human activity. In the zone of discharge of the purified effluent of the Baikal pulp and paper mill some restructuring of the benthic biocenoses has already occurred. Four species of mollusks were found in the local zone where cellulose and lignin are deposited on the bottom. The groups of microorganisms have also changed. All of these changes have been induced by the effluent, the mineral salt content of which conforms to the level established for potable water. The results of many years of study suggest that it is practically impossible to protect such lakes and streams from pollution unless consideration is given to their specifics. Attention must be given to the species composition therein, physiology and functioning of the organisms which populate them, the stability and reproduction of hydrobiocenoses, the geographic position of the lake, its size, depth and volume of water in it, and other factors. Only when these are considered can measures be developed to preserve water quality, the natural properties of lakes and the surrounding plant and animal life. (Baker-FRC)

MANAGEMENT OF THE WATER-TABLE IN ALSACE. PROPOSAL FOR A PATRIMONIAL MANAGEMENT (LA GESTION DE LA NAPPE PHREATIQUE D'ALSACE. PROPOSITION POUR UNE GESTION PATRIMONIALE),
P. Gendrin.
Techniques et Sciences Municipales, No 2, p 89-92, February, 1981. 6 Ref.

Descriptors: *Water resources development, *Water quality management, Water management, Management planning, Groundwater management, Administrative agenies, France, Alsace.

Due to the favorable conjunction of the limits of the Alsatian region and of the presence of a very important groundwater reservoir, it is proposed that a regional patrimonial institution be created to manage the Alsatian water resource at its sources--both surface and underground--prior to any appropriation for exploitation of this water. The aim of such a regional institution would be to preserve the quality of the groundwater, which is currently inadequately protected against pollution from the soil surface which results from the remarkable economic development and urbanization which has occurred in Alsace during the last decades. The proposed solution involves resorting to a water resources management program proceeding on multiple levels and through multiple partners. It is recommended that the management be of the patrimonial type and take into account, before any decision regarding water resources, all present and future concerned interests. (Carroll-FRC)

CALIBRATION OF LARGE-SCALE ECONOMIC MODELS OF THE AGRICULTURAL SECTOR AND RELIABLE ESTIMATION OF REGIONAL DERIVED DEMAND FOR WATER,
California Univ., Davis. Dept. of Agricultural Economics.
R. E. Howitt.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110857, Price codes: A03 in paper copy, A01 in microfiche. California Water Resources Center Completion Report, Univ. of California, Davis, August 1983. 32 p, 9 Fig, 3 Tab. OWRT A-087-CAL(1).

Descriptors: *Model studies, *Regional planning, *Calibrations, *Linear programming, Costs, Water resources planning, Water resource management, *Water demand, Irrigation, *California.

Given the importance of regional response in physical and economic terms to water resource planners, large scale regional models are a widely used component of water resource management. Given the absence of a sufficiently rich data base to estimate cost functions by econometric approaches, linear constrained optimization models have been extensively used to derive normative estimates of former response to water policy. A long standing problem in linear models is the inevitable trade-off between the precision of calibration

f the model and the constrained nature of the olution. Often model results significantly depart om empirical reality with deleterious effects on olicy. This research shows that a nonlinear cost nction formulation overcomes the constraint roblem when the function parameters are estimat- d from actual farmer responses. The Positive Qua- ratic Programming (PQP) theory developed was pplied to the California Agricultural and Re- ources Model (CARM) and used to estimate emand functions for irrigation water by region. UIDELINES FOR INTERACTIVE COMPUT- R SOFTWARE IN WATER RESOURCES EN- INEERING,
dvanced Engineering Software, Irvine, CA.
. V. Hromadka, J. M. Clements, and G. L. uymon.
Vater Resources Bulletin, Vol 19, No 1, p 91-96, ebruary, 1983. 3 Fig, 5 Ref.

Descriptors: *Water resources development, Computers, Hydrology, Microcomputers, Programming, Training, Software, Decision making, Water management, Planning.

A case study is presented in the preparation of umanized computer software for water resources ngineering studies. Considerations are included of vhat should be in a computer software library evelopment plan. A brief presentation of human- zed software guidelines is included along with the se of the programming techniques for computer ided design. The techniques presented provide an pplication of state-of-the-art programming tech- iques to water resources engineering program- ing needs. By establishing a uniform user-friendly et of program guidelines at an agency or firm, the rogram training expenditure associated with new rogram users is minimized. Additionally, errors in rogram usage is virtually eliminated due to the ase of program use. The techniques provided are mployable on most computers of the mainframe nd minicomputer classes, as well as many current- y available microcomputers. Generally, no formal raining is needed for program use, and no pro- ram user's manuals are needed. Since water re- ources related studies and design problems gener- lly involve significant computational effort with nultiparameter models, the capability to conduct everal studies exploring various design alterna- ives or model parameter sensitivity is needed. However, by using humanized software the costs f such iterative studies is significantly reduced. For example, a Southern California runoff hydro- graph procedure generally costs about 40 man ours of a hydrologist's time. Using humanized rogramming, a hydrograph can be developed in ess than 10 minutes' time. Consequently, water esources firms should explore and incorporate a tandard humanized software plan into their com- any software development program. (Baker-FRC)

WATER CONSTRAINTS ON ENERGY DEVEL- OPMENT: A FRAMEWORD FOR ANALYSIS,
California Univ., Berkeley. Div. of Energy and Environment.
J. Harte.
Water Resources Bulletin, Vol 19, No 1, p 51-57, February, 1983. 1 Fig, 14 Ref.

Descriptors: *Water resources development, *Energy conservation, Water supply, Drought, Energy sources, Fuel, Water demand, Management, Decision making, Stochastic processes.

A study of the impacts of future energy development on freshwater resources was carried out as part of the US National Academy of Sciences' CONAES study. The results led to the identification of severe constraints on US energy development that could arise in the future due to geographic and temporal variability of the freshwater resource. In order to obtain a rational resolution of the political problems that will be generated in the future it is necessary that planning based on predictions of future energy supply and demand be replaced by scenario or 'what if' analyses; that full attention be paid to the uncertainties in per-unit-energy water requirements; that suitable stochastic measures of water availability be used to compare water supply with water demand; that realistic ecological criteria, and other alternative use criteria, be developed for estimating impacts of water withdrawn or consumed for energy development; and that human consequences of ecological impacts be described in a manner that will allow the political process to intervene in an optimum manner to allocate water resources. (Baker-FRC)

URBAN STORMWATER MANAGEMENT NEEDS IN NORTH CAROLINA,
North Carolina State Univ. at Raleigh. Dept. of Civil Engineering.
H. R. Malcom, and J. M. Sappington.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-113687, Price codes: A06 in paper copy, A01 in microfiche. Water Resources Research Institute Report No 199, August 1983. 111 p, 10 Fig, 11 Tab, 36 Ref, 2 Append. OWRT B-116-NC(1), 14-34-0001-9125.

Descriptors: *Storm runoff, *Institutional constraints, Stream degradation, Stream erosion, *Urban watersheds, *North Carolina, *Stormwater management, Water quality.

Current practices in stormwater management were examined to provide recommendations for improvement, particularly in the areas of institutional arrangements and technical support. Because of fragmented institutional arrangements and site-specific conventions of design, the network of urban streams suffers from lack of comprehensive treatment of problems of flooding, sedimentation and inferior water quality. If public perception of the value of a better-performing urban stream system is sufficiently well formed to support systematic improvement, the approach recommended is to reform the current fragmented system into a stormwater public utility in parallel to those of water, sewer and street systems. Set at the local level, the public-utility approach would provide for the needed comprehensive planning, design and management. The principal analytical resource needed is that of watershed modeling to simulate urbanizing watersheds adequately for making the planning and design decisions respecting the interactions of system components. A micro-computer program was prepared which uses impulse analysis for the study of streambank behavior under the influence of varying hydrograph shapes. The program, user instructions and case studies are given. An annotated bibliography of reference materials on project topics is included.

CONSTRUCTION OF AN INTEGRATED AND ECONOMICALLY EFFICIENT WATER ALLOCAION PROCESS FOR THE FLINT RIVER,
Georgia Univ., Athens. Inst. of Natural Resources.
H. F. Wright, and R. M. North.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-117241, Price codes: A04 in paper copy, A01 in microfiche. Environmental Resources Center Report No ERC 15-83, Georgia Inst. of Technology, Atlanta, September 1983. 50 p, 2 Fig, 1 Tab, 35 Ref. OWRT A-104-GA(1), 14-34-0001-2111.

Descriptors: Allocation, Flint River Basin, *Georgia, Water budget, State water plan, *Water allocation, *Water law, *Water permits, Water prices, Water resources management.

The economic theory of common property resources, as they exist in the Flint River Basin, are described as a prerequisite to establishing a river basin management strategy. Three alternative approaches are presented as they might be applied to a management strategy that integrates water quality with water supply decisions for both surface waters and ground waters. The principal focus is on identifying the relationship between existing legal institutions and economically optimum allocation mechanisms. Specific management concerns are identified for the Flint River Basin and each concern is addressed in terms of the implications of a proposed marketable water rights system that would include water quality (pollution rights) and water supply (withdrawal rights). This type of system would be implemented only as overall scarcities of the water resources increased its value substantially above any transaction costs of establishing the system. The trading aspect will be many years off but the principle of allocations is sequentially higher valued uses through the effluent withdrawal permitting processes on a gradual (attrition type) basis.

WATER RESOURCES PLANNING IN THE SUSA-BASIN BY MEANS OF A SIMULATION MODEL,
Technical Univ. of Denmark, Lyngby.
J. Knudsen, and D. Rosbjerg.
Nordic Hydrology, Vol 13, No 5, p 323-338, 1982. 18 Fig, 1 Tab, 4 Ref.

Descriptors: *Water resources planning, *Model studies, Susa Basin, Denmark, Catchment areas, Water supply, Waste water disposal, Recreation, Irrigation, Water use, Water demand, Planning.

As part of the Susa project a combined hydrological/water quality simulation model was developed for water resource planning purposes. The model provides a detailed analysis of the consequences of meeting the demands of conflicting interests, including water supply, wastewater disposal, irrigation, and recreation. The recognition of the mutual dependency of each of these interests is crucial to ensure overall coordination of water resources utilization. This recognition is indispensable for providing a sound basis for political decisions on future water resource developments. It is shown that it is possible to establish a unified system of models, enabling multiple effects of water resource dispositions to be analyzed. By employing such models to assess hydrological, water quality and economic impacts of different alternatives, the information base for the final decisions can be substantially improved. (Baker-FRC)

M. Rapinat.
Aqua, No 1, p 241-244, 1981. 7 Fig.

Descriptors: *Automation, *Personnel management, *Manpower, Computers, Water treatment facilities.

Automation in water services in the past has profoundly shaken the structure and organization of personnel in this industry. It is likely that the new forms of automation currently being considered for application in water management will bring changes affecting new groups of personnel in this field. In the past, automation was implemented to economize on the use of technical personnel and to increase the effectiveness of certain water purification stages. These changes resulted in an improvement in working conditions, a reduction in posted personnel, and a significant need for re-training in the use of new techniques, which resulted in an improvement of employee qualifications. These changes had no significant effect on administrative

activity. However, the efficiency and flexibility of new automation devices based on programming will have a considerable effect on requirements for administrative personnel and only a minor effect on the need for personnel in the technical domain. The objectives of these types of automation will be to improve the economic factors bound to operation, to reduce the number of posted personnel, and to further improve working conditions. Current progress in automation in water services can be expected to result in cost reduction, water quality improvement, improved working conditions, and upgrading of personnel. (Carroll-FRC)

6C. Cost Allocation, Cost Sharing, Pricing/Repayment

ANALYSIS OF TAX INCENTIVES FOR INTENSIVE IRRIGATION DEVELOPMENT IN THE NEBRASKA SANDHILLS,
Nebraska Univ.-Lincoln. Dept. of Agricultural Economics.
M. E. Baker.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-110782, Price codes: A02 in paper copy, A01 in microfiche. Nebraska Water Resources Center Completion Report, September 1983. 12 p, 3 Ref, 1 Append. OWRT A-070-NEB(1), 14-34-0001-2129.

Descriptors: *Land development, *Investment, *Tax rate, Regulations, Management analysis, Farm managment, Irrigated land, *Economic justification, Economic prediction, Benefit-cost analysis, *Nebraska, Tax incentives, Irrigation development, Cash flows, Return on equity.

The overall objective was to quantify tax incentives for concentrated irrigation development in the Nebraska Sandhills. Budgets for investments, costs and returns for crop production and analysis of resulting income tax liabilities were simulated for case studies of irrigation developers who were: (1) ranchers, (2) farmers, (3) long-term investors, and (4) short-term investors. The unit of analysis was one center pivot system on a quarter section of former Sandhills rangeland. The returns on equity ran over 60% per year in some years for some investors. Likewise, returns of 4 to 6% per year were also common. The wide range reflected the effects of income tax regulations which permit deduction of interest and depreciation. The short-term investors maintain high returns on equity by liquidating after every fifth year. Reinvesting to tax shelter this income permits the development of 3 new quarters from the proceeds of the first one. For most investors, before-tax cash flows were negative until the loan on the well and center pivot was retired. Thus, for most investors, nonfarm income or income from other farm enterprises was required to supplement revenue from irrigated crop production during the repayment of well and pivot loans. After-tax cash flows were positive for all simulated cases. The flows increased with increases in leverage and marginal tax rates.

COMMENTS ON THE NATIONAL WATER COUNCIL'S CONSULTATION PAPER 'CHARGING HOUSEHOLDS FOR WATER'.
Journal of the Institution of Water Engineers and Scientists, Vol 35, No 2, p 105-108, March, 1981.

Descriptors: *Water metering, Economic justificaton, *Water rates, Economic aspects, *Economic feasibility, Cost sharing, Expenditures, Marketing, Payment, Prices, *Domestic water.

The Institution of Water Engineers and Scientists have replied to the National Water Council's paper dealing with various methods by which households could be charged for water service. Three major issues have necessitated changes in charging policies as they now stand. These influences were: the Water Act of 1973, which imposed a legal requirement on water undetakings to introduce charging systems by April of 1981 that show no undue preference or discrimination between classes of ratepayers; the introduction of direct billing by water authorities, highlighting the cost of combined water services; and the highly capital-intensive character of the water industry's operations, leading to more than half of the revenue from charges being absorbed by the servicing of capital expenditure, thus causing faster increases in consumers' charges than the general rate of inflation. The Institute notes that there is a clear attempt to improve the efficiency, reliability and general technology of metering. However, it is suggested that optional metering is to some degree a financial palliative. The Institute feels that the actual adoption of metering will not be significant except than in the commerical sector. The thoughts of a member of the Institute are also published; he urges that further consideration be given to how other countries manage their charging systems before moving toward optional metering. IMPACT ON RESIDENTIAL WATER CONSUMPTION OF AN INCREASING RATE STRUCTURE,
Pennsylvania State Univ., University Park. Inst. for Research on Land and Water Resources.
C. E. Young, K. R. Kinsley, and W. E. Sharpe.
Water Resources Bulletin, Vol 19, No 1, p 81-86, February, 1983. 3 Fig, 4 Tab, 20 Ref.

Descriptors: *Water conservation, *Water rates, Water supply, Water resources development, Economic aspects, Public policy, Metering, Pricing.

A two-step procedure is described for use in estimating the impact of an increasing rate structure on residential water use. An error components regression procedure is used to estimate demand relationships for a period prior to the rate change. Water use is predicted for the post rate change period, assuming that the rate structure was not changed. Comparison of actual with predicted use indicates that water use declined as a result of the imposition of the increasing rate structure. Average residential water use in the WSSC's service area has been decreasing since 1974. A portion of this decreasing trend can be attributed to the overall success of the WSSC's water conservation programs. Additional reductions in water use resulted from the imposition of an increasing rate structure for water on January 1, 1978. Comparison of actual use with estimated use, assuming that the increasing rate structure was not instituted, revealed that actual use decreased in 1978 and 1979. Estimated reductions in water use ranged from 1.1 to 8.7%. A portion of this decreased use can be attributed to changes in water use habits. It remains to be seen whether or not these habit changes are maintained after the WSSC's customers become accustomed to the new rate structure. (Baker-FRC)

CHANGES IN WATER POLICY IN THE PEOPLE'S REPUBLIC OF CHINA,
Purdue Univ., Lafayette, IN. Dept. of Political Science.
L. Ross.
Water Resources Bulletin, Vol 19, No 1, p 69-72, February, 1983. 2 Tab, 9 Ref.

Descriptors: *Water policy, *Metering, *Water demand, Water use, Conservation, Water conservation, *China, Policy, Public policy, Regulations, Economic aspects.

A major change has taken place in the last few years in the regulation of water usage in China. This change was encouraged by the occurrence of severe drought in the north China plain, including the politically important cities of Beijing and Tianjin. The drought enhanced the prominence of economics as part of the current modernization drive (control of water use through price regulation). China's cabinet recently committed the country to the introduction of metering and usage sensitive pricing along with other conservation measures. However, the speed at which metering can actually be carried out and the quality of managment which will be given the endeavor are uncertain at this time. The high hopes currently placed on these measures may be exaggerated. Since individual meters will be costly to install and difficult to monitor, group meters are likely to be widespread creating problems of group incentives and mutual supervision. Further, utility companies which are owned by the state may require additional rate making assistance if their sales decline too precipitously. China's present consumption also is very low. As the economy develops additional water supplies will be required, although market solutions should reduce and slow down the need for new supplies. Political opposition may yet arise in response to the wide use of markets to force conservation, as this would be ideologically opposed to much of the political climate in the country. (Baker-FRC)

PRICING AS A POLICY TO REDUCE SEWAGE COSTS,
Maryland Univ., College Park. Dept. of Agricultural and Resource Economics.
M. Strudler, and I. E. Strand, Jr.
Water Resources Research, Vol 19, No 1, p 53-56, February, 1983. 1 Tab, 16 Ref.

Descriptors: *Costs, *Wastewater treatment, *Pricing, *Maryland, Elasticity of demand, Water rates, Economic aspects, Water pollution control.

Compliance with the Federal Clean Water Act is expected to cost $3 billion for the state of Maryland, of which $1 billion must be paid by the citizens and $2 billion is available from federal grants. Reducing sewage flows by charging a modest water/sewage fee for residential water use ($2 per thousand gallons) would reduce costs of compliance by a total of $21 million. Of 61 facilities, 29 charge nothing for use or disposal of water and 16 have a per capita daily use greater than 100 gal. Twenty-one towns with no water charge or a water charge less than $2 per thousand gal and a daily per capital use of more than 100 gal were used in a cost analysis. Raising the water charge to $2 per thousand gal in these towns would reduce daily sewage flow by 1.9 million gal and reduce annual costs by $14.4 million. Largest cost savings would be in Patpsco ($5.3 million), Savage, ($1.6 million), Bowling Green ($1.5 million), Frederick ($1 million), and Chestertown ($910,000). The elasticity of disposal demand was estimated to be -0.07. Thus a 14% increase in prices would decrease sewage flow by about 1%. (Cassar-FRC)

D. T. Kao, and S. L. Rusher.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-111749, Price codes: A06 in paper copy A01 in microfiche. Research Report No 146, September 1983. 104 p, 17 Fig, 14 Tab, 36 Ref, 2 Append. OWRT A-089-KY(1), 14-34-0001-2119.

Descriptors: *Water demand, *Water allocation, Slurries, Pipe flow, Pipelines, Coal, *Water requirements, *Coal slurry pipelines, Coal slurry transportation, Coal slurry pipeline design.

The amount of water required for coal slurry transportation is a function of coal properties and the magnitude of coal movement. The pipeline system characteristics and the method of slurry preparation also effects the overall water requirement of the system. In the present study methodologies are developed based on reported and modified coal slurry flow correlation equations to determine the quantity of water needed under various

coal transport and flow conditions. Auxiliary water requirements including start-up and flushing water storage; related evaporation and seepage losses are also included. A computer program and several monographs are presented to provide a quantitative estimation of water requirements for fine to coarse coal slurry transport. The results are useful to the slurry pipeline design engineers in providing essential information for state and local water allocation policy determination.

DEVELOPMENT OF A PROTOTYPE SOFTWARE PACKAGE FOR PROJECTING WATER DEMAND AT THE SUBCOUNTY LEVEL,
Delaware Univ., Newark. Coll. of Urban Affairs and Public Policy.
E. C. Ratledge.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-117258, Price codes: A03 in paper copy, A01 in microfiche. Delaware Water Resources Center Completion Report, October 1983, 36 p, 24 Tab. OWRT A-057-DEL(1), 14-34-0001-2108.

Descriptors: *Data processing, Population dynamics, Planning, Growth rates, *Water demand, Water management, Administrative decisions, Water use, Projections, Water distribution, Mathematical studies, Prediction, Public policy, *Delaware, *Local governments.

A prototype software package which would produce alternative estimates of water demand at the subcounty level was developed. The design dictated the use of data which was routinely available in a large number of jurisdictions. Further, the software had to be flexible in order to allow testing of alternative assumptions and to accept new data as actual population, employment, or water demand data became available. The tool is designed for use by managers of water resources; however the design is flexible enough to permit estimation of many population-based service demands.

Descriptors: Drinking water, Erosion, *Georgia, Groundwater, Hazardous waste, *Legislation, Marshland protection, Permit systems, Pollution control, *Regulation, Sedimentation, Shore protection, Surface water law, Water administration, *Water allocation, *Water law, *Water permits, *Water quality, Water quality protection, Wetland protection.

In the decade of the 70's, the Georgia and Federal legislatures virtually rewrote the body of substantive law affecting water resources. The approach of the Georgia legislature, that portion of the law of the period which is addressed in this report, was to initiate change in areas it perceived needed to be changed and to respond positively to Federal initiatives that otherwise would have preempted State authority in broad areas of natural resources/water law traditionally administered by the State. The result has been an important accumulation of statute law and regulation which treats comprehensively the important issues of water resource protection and allocation.

Descriptors: *Institutional constraints, *Legal aspects, *Local governments, Water districts, *Political constraints, Political aspects, Utilities, Utility extension, *Urban planning, Community development, Water supply, Municipal water, Municipal wastewater, *Utah, Salt Lake County.

Urbanizing areas throughout the nation are considering governmental reorganization or consolidation to coordinate planning and improve the cost effectiveness of the delivery of public services. More efficient water supply and wastewater services may become important in the political debate over reorganization. However water factors figure politically, accomplished reorganizations must carefully plan for efficient provision of water services. This study profiles the structure and interactions of municipalities and water service agencies in Utah's Salt Lake County during the 1970s. Both 1975 and 1978 attempts to consolidate Salt Lake City and the unincorporated area of the County failed. The voting patterns, interest group positions, and issues are examined. One major water issue surfaced in a concern that service jurisdictions and financial obligations were not sufficiently defined to protect the communities previously bound through water service agreements but excluded from the consolidated government. Additionally, the proposed dissolution of the County water conservancy district raised doubts on the division of equity in water rights and distribution facilities. Any large water development stabilizes institutional arrangements to a degree which may become a financial and legal constraint to desired change. Overall, nonwater issues dominated the decision in this water sensitive area. This implies that water service jurisdictional alignments are set by political decisions based on nonwater considerations. Water utilities must do their best to be effective in the resulting context.

Descriptors: *Water law, *Water rights, *Appropriation, Boundary disputes, Liability, Negligence, Ownership of beds, Permits, Property boundaries, *Riparian rights, *Oregon.

Oregon water law was initially based upon the riparian and appropriative doctrines as proprietary systems for the allocation of water resources. State interest was first asserted systematically in the 1909 Surface Water Code. It abolished inchoate riparian rights, provided for the adjudication of pre-1909 vested rights, established a permit system for surface water use, and provided for state administration of water rights. Various enabling statutes have since provided for eight water management districts. Over time, the legislature withdrew streams from appropriation for scenic and municipal water supply purposes. A 1927 Groundwater code was applied to eastern Oregon. It was replaced in 1955 by a comprehensive Groundwater Act. Also in 1955, a water planning statute created a Water Resources Board with authority to classify waters for future use and to establish minimum stream flows for fish life. Since 1955 planning has been accomplished though 12 basin program statements; 19 watermaster districts provide field assistance and enforcement water laws. In 1975 the Oregon legislature merged the State Engineer's office and the Water Resources Department. Since 1975, a basic problem has been the scarcity of funds to complete adjudications, to establish critical groundwater areas, to staff the 19 watermaster districts, and to update the 12 basin program statements. The effort to determine navigability and state ownership of the beds of navigable streams was aborted by the 1983 legislature. The 1983 legislature also emphasized the creation of minimum stream flows. Oregon has considerable case law on problems relating to water boundaries, water drainage, and liability for escaping water.

THE CONTINUING EVOLUTION OF AN AUSTRALIAN WATER RESOURCES POLICY,
Macquarie Univ., North Ryde (Australia). School of Earth Sciences.
P. Crabb.
Water Resources Bulletin, Vol 19, No 1, p 23-28, February, 1983. 1 Fig, 1 Tab, 42 Ref.

Descriptors: *Water resources development, *Legislation, *Australia, Regulations, Policy, Water management, River Murray, Rivers, Water demand, Water supply.

The limited water resources of Australia highlight the need for policy guidelines for water management. A gradual evolution of a national water resources policy took place during the 1970s, facilitated by a nationally agreed statement of objectives and culminating in a federal policy statement presented in 1979. However, the Australian constitution delegates the major responsibility for water resources to the states. The federal policy statement seems to assume that each state has a water resources policy and that it accords with the nationally agreed objectives. This is not the case, and the practical management of Australia's water resources falls short of the principles set out in the document of policy. The River Murray, which is the nation's major water resource, provides ample evidence of this fact. In view of its very limited water resources it is urgent that Australia reduce the disparity between principle and practice in their management. (Baker-FRC)

Environmental Resources Center Report No ERC 14-83, Georgia Inst. of Technology, Atlanta, September 1983. 87 p, 6 Fig, 7 Tab, 9 Ref. OWRT A-094-GA(1), 14-34-0001-1111.

Descriptors: *Georgia, *State agencies, Local governments, Comprehensive management, *Govern-

ment agencies, *Institutional arrangements, Multiple objectives, Water resources management.

The natural resources of water quality, water quantity, surface water, and ground water are currently managed through water programs in various federal, state and local agencies. More efficient water management and resources utilization would result if agency programs were better coordinated to manage the water resources and water users as a system. This report seeks to facilitate more coordinated water resources management by providing a compilation and summary of water management activities by local, state, federal, and private organizations in Georgia.

SETTING EFFLUENT AMMONIA LIMITS TO MEET IN-STREAM TOXICITY CRITERIA,
Washington State Dept. of Ecology, Olympia.
W. E. Yake, and R. K. James.
Journal of the Water Pollution Control Federation, Vol 55, No 3, p 303-309, March, 1983. 7 Fig, 11 Ref.

Descriptors: *Ammonia, *Regulations, Effluents, Legislation, Decision making, Monitoring, Water pollution control, Water quality control, Quality control, Seasonal variations, *Toxicity, Effluent standards, Effluents, *Water quality standards, *Washington.

Statewide policy guidelines for setting effluent ammonia limits are presently being sought by the Washington State Department of Ecology. A method for setting effluent ammonia limits that protect against in-stream, un-ionized ammonia toxicity is described. The method described uses fixed-station, long-term receiving water data and river flow records to establish seasonal effluent limitations. Seasonal limits provide the ability to meet the in-stream criterion with a high degree of reliability while simultaneously minimizing the need for additional construction of treatment works and higher operating costs at treatment facilities. This desirable result is particularly marked in the case of un-ionized ammonia, because it turns out that this highest risk season, summer at low flow, is also the season during which in-plant nitrification is most easily achieved and maintained. The method accounts for seasonal functions in pH, temperature, flow, and background ammonia concentrations. It can be applied consistently across the state. It uses currently available data, and thus delays in data collection and lack of the resources needed to plan, execute, and publish intensive receiving water survey results are not a problem. The method is also flexible enough to accommodate policy decisions needed to implement the method. (Baker-FRC)

THE IMPACT OF FLOODPLAIN REGULATIONS ON RESIDENTIAL LAND VALUES IN OREGON,
Oregon State Univ., Corvallis. Dept. of Geography.
K. W. Muckleston.
Water Resources Bulletin, Vol 19, No 1, p 1-7, February, 1983. 4 Fig, 2 Tab, 2 Ref.

Descriptors: *Flood plains, *Regulations, *Land appraisals, *Oregon, Flood control, Legislation, Non-structural alternatives.

Ambiguities about the relationship between floodplain regulations and residential land values were investigated. Clarification of this relationship should facilitate the long-delayed implementation of a more comprehensive and successful approach to flood hazard mitigation than is presently employed. The suggestion that current floodplain regulations significantly depress appreciation rates of regulated lands relative to those of similar unregulated lands was rejected in most cases. When this suggestion was accepted the circumstances rendered the conclusions tenuous. Problems and issues facing this type of research are presented in case studies of two of the research study areas. However, it is pointed out that conclusions at this juncture should remain tentative because the research could not be carried out under ideal conditions. First, all of the criteria for establishing uniform study areas could not be met, even though much attention was paid to this step in the research process. One particular problem is that considerable development had taken place in some of the study areas prior to the implementation of floodplain regulations. Under these conditions a valid question regarding the relation between regulation and land values appears to be whether any possible negative aspects of land use regulations are not outweighed by the positive attributes of flood insurance, which under the NFIP becomes available concurrent with the implementation of regulations. ENHANCING THE EFFECTIVENESS OF PUBLIC PARTICIPATION IN DEFINING WATER RESOURCE POLICY,
Wisconsin Univ.-Madison. Water Resources Center.
L. -J. Schierow, and G. Chesters.
Water Resources Bulletin, Vol 19, No 1, p 107-114, February, 1983. 1 Fig, 1 Tab, 35 Ref.

Descriptors: *Public policy, Water resources development, *Education, Training, Management, Water management, Decision making, *Water policy.

The scope of the instructional deficiency in the participations of the public in defining policy for water resource development was studied. While millions of dollars are spent annually on public involvement programs, many of the goals for these programs are not achieved. One reason may be the lack of emphasis on educational programming. Professional expertise which is available to guide the development and implementation of instructional programs is not being used, and existing informational programs are inadequate to meet educational objectives. Eleven interdependent educational goals are identified such that achievement of each goal improves the likelihood of achieving others. Evaluations indicate that the incorporation of mechanisms employed by professional educations is a potential remedy to the lack of knowledge apparent at the public level. An individualized educational program is recommended to meet the needs of a heterogeneous adult audience. (Baker-FRC)

6G. Ecologic Impact Of Water Development

A COMMENT ON THE PAPER BY JOHN R. M. KELSO AND GARY S. MILBURN: 'ENTRAINMENT AND IMPINGMENT OF FISH BY POWER PLANTS IN THE GREAT LAKES WHICH USE THE ONCE-THROUGH COOLING PROCESS, (J. GREAT LAKES RES. 5:182-194, 1979),
Toledo Edison Co., OH.
J. Scott-Wasilk, R. Kunshek, D. T. Michaud, A. E. Gaulke, and J. H. Balletto.
Journal of Great Lakes Research, Vol 7, No 4, p 491-497, 1981. 3 Tab, 23 Ref.

Descriptors: Fish populations, *Entrainment, *Impingement, Powerplants, Hydroelectric plants, Cooling, Great Lakes, *Fish handling facilities.

An evaluation is presented of an earlier assessment of entrainment and impingment impact of the 89 steam-electric generating stations on Great Lakes fish stocks. The original evaluation inappropriately compared 1975-76 impingement losses to outdated commercial catch statistics for years prior to 1970. More recent statistics for one region of the Great Lakes which has supported a commercial fishery for almost 100 years document the supposition that the commercial catch is increasingly dominated by ecologically less desirable, but very abundant species. The earlier evaluation stated that 85% of the total numbers of fish impinged and entrained are of these very abundant species. Despite the large numbers of impinged and entrained fish, the numbers of alewife caught commercially in Lake Michigan have been steadily increasing over the past several decades. The earlier report estimated that large numbers of fish larvae were entrained and killed at power plants. However, as with impingement, the impact of the large number of larvae entraind is small when compared with the probable total number of larvae in the lakes. Entrainment losses in the earlier study are also represented as improbably severe in that entrainment mortality is assumed to be 100%, whereas it has been shown to vary between 30 to 100% depending upon species and life stage. This evaluation concludes that the power plant entrainment and impingement have only a minimal impact on the fisheries of the Great Lakes. This evaluation is responded to by an author of the original paper, who maintains that once-through cooling extracts fish which are not utilized in any way and which are in excess of 25% of the total annual commercial fish havest. PRODUCTION OF FILTER-FEEDING TRICHOPTERA IN AN IMPOUNDED AND A FREE-FLOWING RIVER,
Royal Ontario Museum, Toronto. Dept. of Entomology.
C. R. Parker, and J. R. Voshell, Jr.
Canadian Journal of Zoology, Vol 61, No 1, p 70-87, 1983. 2 Fig, 8 Tab, 65 Ref.

Descriptors: *Aquatic productivity, *Dam effects, *Ecological effects, Aquatic population, *Food chains, *Zooplankton, Aquatic animals, Environmental effects, Crustaceans, Trophic level, Population dynamics, Reservoirs, Seston, *Virginia, North Anna River, South Anna River.

The productivity of five species of Hydropsychidae and two species of Philoptamidae was examined at two sites on the impounded North Anna River and two sites of the free-flowing South Anna River of Virginia. Total production was highest at the site immediately below the dam (3250.0 kilograms dry weight/ha/yr), while at the other sites production ranged from 94.0 to 515.1 kilograms dry weight/ha/year. Analyses of trophic dynamics, seston energetics, and rates of consumption showed that zooplankton released from the reservoir greatly enriched the seston which corresponded to the size of the zooplankton released from the reservoir and the capture net mesh size of the hydropsychids. The high density of filter feeders below the dam reduces the food quality of the seston and limits production downstream. Detailed biotic interaction which might effect the dynamics of such an ecosystem are also considered. (Geiger-FRC)

NFLUENCE OF A NEW IMPOUNDMENT ON PESTICIDE CONCENTRATIONS IN WARM-WATER FISH, SAYLORVILLE RESERVOIR, DES MOINES RIVER, IOWA, 1977-78,
Minnesota Pollution Control Agency, Roseville.
S. Y. T. Leung, R. V. Bulkley, and J. J. Richard.
Pesticides Monitoring Journal, Vol 15, No 3, p 117-122, December, 1981. 1 Fig, 3 Tab, 10 Ref.

Descriptors: *Fish, *Reservoirs, *Pesticide residues, Fate of pollutants, Rivers, Insecticides, Herbicides, DDT, Dieldrin, Heptachlor, Saylorville Reservoir, *Iowa, Des Moines River.

Pesticide concentrations were determined in warm water fish caught above, within, and below the newly impounded (April 1977) Saylorville Reservoir, on the Des Moines River, Iowa, from October 1977 to October 1978. No atrazine, alachlor, or cyanazine were detected in fish samples. Dieldrin generally occurred in greater concentrations than the other insecticides identified, total DDT and its isomers and heptachlor epoxide. Levels of dieldrin and heptachlor epoxide were significantly higher in river carpsucker from the reservoir than from the river. Other fish species (gizzard shad, common carp, channel catfish, white crappie, walleye, and largemouth bass) showed no trends in pesticide levels as related to site of collection. Mean pesticide concentrations (micrograms per kg wet weight) for all fish at the reservoir and downstream stations were: dieldrin, 49-55; total DDT, 65-72; and heptachlor epoxide, 6-9. (Cassar-FRC)

INTEGRATING A GROUND WATER DATA RECONNAISSANCE PROGRAM INTO A MINERAL EXPLORATION PROGRAM,
Mobil Coal Producing, Inc., Denver, CO. Environmental Technical Services.
J. M. Kaufman, and T. D. Vandell.
Mining Engineering, Vol 35, No 2, p 137-139, February, 1983. 4 Fig.

Descriptors: *Mineral industry, *Geohydrology, *Exploration, Drilling, Groundwater, Data collection, Water quality, Water level.

Costs may be saved by integrating a groundwater data reconnaissance program into the later phases of mineral exploration. Water data is most easily obtained from exploration holes drilled with rotary drilling equipment using air or water as the drilling fluid. For each borehole a geologic and geophysical log should be kept and water samples collected for analysis. Hydrogeologic data which can be obtained from these studies include static water levels, permeability, air lift production rate, transmissivity, and water quality. (Cassar-FRC)

EVALUATION OF WATER QUALITY SAMPLING LOCATIONS ON THE YUKON RIVER,
Inland Waters Directorate, Vancouver (British Columbia). Pacific and Yukon Region.
P. H. Whitfield.
Water Resources Bulletin, Vol 19, No 1, p 115-121, February, 1983. 4 Fig, 5 Tab, 14 Ref.

Descriptors: *Water quality, *Evaluation, *Sampling, Samples, Yukon River, *Alaska, Yukon Territory, Monitoring.

An approach was developed and used to evaluate sampling locations on the Yukon River between Dawson in the Yukon Territory and Eagle, Alaska. Spatial heterogeneities and temporal variations in a number of water quality variables at four locations on the Yukon River were examined to determine an optimum sampling location and to estimate a necessary frequency and density of sampling for long term monitoring. At three of the four study sites it was difficult to obtain representative samples due to the presence of extensive lateral heterogeneities. These heterogeneities occur because of a lack of mixing between the Yukon River and the major tributaries upstream from Dawson. Only one of the sampling locations was spatially homogeneous enough to provide representative samples. Concentration variations over the annual cycle are very large, often as much as two orders of magnitude. Estimates are made of the frequency and density with which samples must be collected to be able to detect a 10% difference between annual mean concentrations. The estimated frequencies are so large that such an undertaking would be impractical. More importantly, the assumptions of this analysis are invalid, and time series analysis of fixed frequency samples is proposed as an alternative that is statistically rigorous and requires fewer samples. SAMPLING ACCURACY OF PIT VS. STANDARD RAIN GAGES ON THE FERNOW EXPERIMENTAL FOREST,
Northeastern Forest Experiment Station, Parsons, WV. Timber and Watershed Lab.
J. D. Helvey, and J. H. Patric.
Water Resources Bulletin, Vol 19 No 1, p 87-89, February, 1983. 2 Fig, 1 Tab, 14 Ref.

Descriptors: *Rain gages, *Measuring instruments, *Rainfall, Gages, Precipitation, Sampling, Standard raingages, Pit gages, Hardwood forest, Forest management, Forestry, *West Virginia.

Catch in standard (unshielded) rain gages exposed 3 feet above the surface of the land was compared with catch in pit (buried) gages exposed 1 inch above the surface. The results of the comparison confirm that pit gages can help to rectify the undersampling of rainfall inherent in conventionally exposed standard gages, in wildland observation as well as the usual weather stations. They confirm also that trees surrounding rain gage openings in the forest provide wind shielding inadequate to correct the undersampling in standard gages. Catch in buried gages may reflect orographic increases in rainfall more accurately too; precipitation is known to increase 4 to 8 cm/yr/100 m of elevation. This relation between elevation and precipitation is undetectable in long-term Fernow data based on catch in standard gages, presumably because it is masked by the undersampling effect of stronger winds at higher elevations. Pit gages caught significantly more rain than did standard gages at each of the four locations tested. Catch increases ranged from 213 to 3.4%. (Baker-FRC)

AUTOMATED PATTERN RECOGNITION OF PHYTOPLANKTON - PROCEDURE AND RESULTS,
Technische Univ., Dresden (German D.R.).
O. Schlimpert, D. Uhlmann, M. Schuller, and E. Hohne.
Internationale Revue Der Gesamten Hydrobiologie, Vol 65, No 3, p 427-437, 1980. 6 Fig, 1 Tab, 5 Ref.

Descriptors: *Automation, *Phytoplankton, *Classification, Asterionella, Fragilaria, Deratium, Melosira, Peridinium, Computers.

Automatic identification of 5 phytoplankton species (Asterionella formosa, Melosira italica, Ceratium hirundinella, Fragilaria crotonensis, and Peridinium bipes) was evaluated using television pictures analyzed by a Robotron 4200 computer. Raster images were subjected to spectral analysis. A feature vector was used to describe the objects independent of their angular position. This permitted characterization in a p-dimension feature space of each genus as a cluster which could be separated from the clusters characterizing other genera by means of discriminance functions. The statistical moments (location and orientation of the separating hyperplanes) required for classification were determined automatically by a learning method. The overall error rate was 6.8%. Errors for individual species were zero for Asterionella, 25% for Fragilaria, and 1-4% for the other 3 species. The rate of rejection (assignment to none of the 5 classes) was 12.8%. The scanning raster used in the study was relatively coarse, (<100 picture elements per colony). (Cassar-FRC)

RESULTS OF TOXIC ACTION OF WATER POLLUTANTS ON DAPHNIA MAGNA STRAUS TESTED BY AN IMPROVED STANDARDIZED PROCEDURE (ERGEBNISSE DER SCHADWIRKUNG WASSERGEFAHRDENDER STOFFE GEGEN DAPHNIA MAGNA IN EINEM WEITERENTWICKELTEN STANDARDISIERTEN TESTVERFAHREN),
Bundesgesundheitsamt, Berlin (Germany, F.R.). Inst. fuer Wasser-, Boden- und Lufthygiene.
G. Bringmann, and R. Kuhn.
Zeitschrift fuer Wasser und Abwasser Forschung, Vol 15, No 1, p 1-6, 1982. 14 Tab, 5 Ref.

Descriptors: *Water pollution effects, *Toxicity, Sublethal effects, Median tolerance limit, Data acquisition.

A largely standardized procedure for testing the potential toxic action of water pollutants as measured by the immobilization of Daphnia magna Straus is presented. Details of the methodology, application, evaluation, and results are discussed. The standardized test strain IRCHA served as a test organism. The stock cultures were fed standardized dry algae, and toxicity testing was performed in a chemically and physically defined standardized culture medium. When evaluating the test results, the medium tolerance limits (EC 50) values of the substances tested were determined according to a mathematically standardized method. The toxicologically relevant range of the EC was determined by establishing the EC 0 and the EC 100. The results of 183 pollutants are listed in tables classified by substance groups. About 30 pollutants were found to toxicologically effective at concentrations of less than 10 milligrams per liter. These pollutants include silver, mercury, copper, thallium, and cadmium cations; dichromate, cyanide, sulphur, arsenate, and selenite anions; such inorganic substances as hydrogen peroxide and ammonium hydroxide; and such organic substances as hydroquinone, 4-nonylphenol, and pentachlorphenol. GEOPROCESSING - A WATER DISTRIBUTION MANAGEMENT TOOL,
D. K. O'Day.
Public Works, Vol 114, No 1, p 41-43, January, 1983. 3 Fig, 3 Ref.

Descriptors: *Data processing, *Water mains, *Geography, *Water distribution, Dual Independent Map Encoding (DIME), Leakage, Data collections, Urban areas, Maps, Rehabilitation, *Geoprocessing.

Geoprocessing combines geographic analysis and data processing. It can be useful in managing water distribution systems by integrating routine, readily available field data into a geographically oriented data system for network analysis models, water loss control programs, and maintenance/rehabilitation planning. The Dual Independent Map Encoding (DIME) base file provides a computerized description of street networks in 256 U.S. metropolitan areas. An example of geographically processing water utility data features preparation of a summary of water main breaks for each segment of the main in the distribution system, given several thousand water main break reports. This report can identify high break mains, leak prone mains,

and low C-value mains to aid in planning rehabilitation programs. (Cassar-FRC)

EVALUATION OF THE ECONOMIC EFFICIENCY OF THE OPERATION OF A HYDROELECTRIC STATION ON THE BASIS OF SPECIFIC WATER DISCHARGES,
G. S. Kiselev, and A. A. Kuprik.
Hydrotechnical Construction, Vol 15, No 9, p 533-538, 1981. 3 Fig, 3 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 9, p 24-26, September, 1981.

Descriptors: *Economic efficiency, *Hydroelectric plants, *Specific discharge, Reservoir operation, Operation policies, Electric power production, Flow measurement, USSR.

The economic efficiency of a hypothetical hydroelectric station was calculated by comprising actual specific discharge and specific discharge determined from the assigned operating regime. This procedure compensates for differences in head and daily load assignments. The resulting efficiencies provide a basis for incentives to operate the plants at maximum efficiency. In addition, a group of interconnected hydroelectric and thermal powerplants may be rated for efficiency on a more uniform basis. (Cassar-FRC)

SHANGHAI TUNNEL PROJECTS SPUR CONSTRUCTION INNOVATIONS,
Shanghai Tunnel Construction Co. (China).
W. Z. Xin.
Civil Engineering (New York), Vol 52, No 12, p 36-38, 1982. 4 Fig.

Descriptors: *Tunnels, *Water conveyance, *Piping, Design criteria, Engineering, Water pipes.

Underground construction in soft ground is newly developed in Shanghai. Pipe jacking was introduced into the area over two decades ago for a short sewer tunnel under a woolen mill workshop. The use of pipe jacking spread, and the long distance record comprised the completion of a 518.99 m push of 2600 mm diameter steel pipe under the Yung River. The major technical innovations of long distance pipe jacking include: the introduction of intermediate jacking stations in association with bentonite lubrication to lower the total thrusting force, which increases in direct proportion to the distance of pipe jacking; and the introduction of an articulated shield which facilitated high accuracy both in alignment and grade. The shield used for long distance pipe jacking is a special design, built on three segments with watertight overlapping joints for articulation. The third innovation was the introduction of presssurized face shield with 'shelves' used to support the sandy or clayey ground. Welded steel pipes were used in the long distance projects both for withstanding the high jacking force and external ground pressures and for watertightness. Reinforced concrete pipes have also been developed to withstand the erosive effect of the effluents in long distance sewage piping. (Baker-FRC)

ON WATER WAVES PRODUCED BY GROUND MOTIONS,
Montpellier-2 Univ. (France). Dept. de Physique Mathematique.
P. C. Sabatier.
Journal of Fluid Mechanics, Vol 126, p 27-58, 1983. 20 Ref.

Descriptors: *Waves, *Model studies, Seismics, Tsunamis, Mathematical equations, Mathematical studies.

A linear and irrotational model is constructed to represent the formation of water waves by ground motions of a sloping bed. A survey of the constant-depth case, given first, helps in understanding the mechanism of formation and, in this oversimplified case, wave propagation away from a source, which is usually very asymmetric. The importance of asymmetry, which produce trapped waves, is illustrated by an estimate of the propagation in a three-dimensional case. The formation of waves by a ground motion on a slope is studied in depth. The problem is reduced to linear integral equations of the first kind. A source-response pair is constructed using an inversion technique. A general approximate solution is derived in both the two and three dimensional cases. Results for the sloping-bottom case are given for small times. They give initial values of surface displacement. They also enable the determination of important physical parameters in the ground motion to be made and the efficiency of wave production to be evaluated. (Baker-FRC)

BEND LOSSES IN DROP INLET SPILLWAYS,
Saskatchewan Univ., Saskatoon. Dept. of Civil Engineering.
C. D. Smith.
Canadian Journal of Civil Engineering, Vol 10, No 1, p 1-8, January, 1983. 8 Fig, 6 Tab, 8 Ref.

Descriptors: *Spillways, *Hydraulic loss, *Eddies, Design criteria, Hydraulic design, Spillway channels, Drop inlet spillway, Bend loss.

Several configurations for the 90 degree bend in drop inlet spillways were subjected to hydraulic tests. Cross sections were square and the ratio of the inside radius of the bend to the side dimension of the cross section was 0.5 for each of the 5 designs: (1) curved bend (both sides curved), (2) square bend (both sides angular), (3) outside curve (outside curved, inside angular), (4) inside curve (outside angular, inside curved), and (5) curve and bevel (inside curved and outside beveled). Loss coefficients determined over a range of flow velocities and heads were: curved bend, 0.27; square bend, 1.3; outside curve, 1.29; inside curve, 0.52; and curve and bevel, 0.37. These results show the importance of the inside curve and the unimportance of the outside curve. Construction costs are considerably higher for curved structures than for the square structure. Therefore design can be simplified by omission of the outside curve while retaining the flat bottom as a convenient base for construction. The inside curve design is an economical and effective compromise between the expensive curved design and the inefficient square bend. (Cassar-FRC)

SIZING WATER WELLS FOR GROUND WATER HEAT PUMPS: PART II,
T. E. Gass.
Water Well Journal, Vol 34, No 5, p 36-37, May, 1980. 1 Fig.

Descriptors: *Storage requirements, *Storage tanks, *Water storage, *Pump wells, *Water pressure, Storage capacity, Pumps, Wells, Water demand, Groundwater, Recycling.

The primary purpose of the pressure tank is to ensure adequate water pressure to all house fixtures while providing enough water storage to avoid frequent pump starts and stops. The storage facility must be large enough to meet peak demands while allowing some reserve. The hydropneumatic pressure tank is commonly used for water storage situations where demand does not significantly exceed pump capacity. In some parts of the country, the well itself may provide substantial storage. Storage tanks should be used only in conjunction with a groundwater heat pump. A pump must be sized to meet the water demand of the heat pump and to deliver the water at a desired pressure. A 2,400 gallon tank will meet the continuous demand of the heat pump for 8 hr even if the family diverts 480 gallons of well water for domestic use. To conserve water, some of the water leaving the heat pump may be recycled back to the storage tank. When heating and cooli needs increase, there must be some input groundwater regulated by thermistors. (Geige FRC)

WATER HAMMER WITH BREAKS IN TH CONTINUITY OF THE LIQUID,
L. S. Gerashchenko.
Fluid Mechanics, Vol 10, No 2, p 135-141, 1981. Fig, 11 Ref.

Descriptors: *Water hammer, *Fluid mechani *Pressure spikes, *Pipelines, Pressure, Wat mains, Pipe flow.

New experimental data are given on the pressu spikes in pipes carrying liquids under conditions water hammer with breaks in the continuity liquid. In the experimental setup, the wa hammer originated at the end of a 51.5 mm dian ter, 46.9 m long steel pipe. The pressure variati that occurred during the first phase fitted the Zh kovskiy theory. The pressure reduction period w longer than the impact phase, which suggests on of breaks in continuity. The start of the third wa hammer phase was accompanied by an instan neous high-frequency pressure spike. Such surg with amplitudes decreasing below that of the pr sure spike, are observed at the start of successi add phases that follow periods of breaks of co tinuity. It is concluded from comparison of t experimental results with the theory of develo ment of cavitation that the pressure spikes res from forces generated by simultaneous collapse individual cavitation bubbles upon overall rise pressure in the liquid. By speeding up the fi travel rate it was possible to obtain larger-sc oscillograms of pressure changes immediately f lowing pressure spikes. The pressure curve dur the phase with maximum possible pressure red tion shows up as a horizontal line. At the end the reduction period there appear small press fluctuations, which precede the spikes. Furth study of oscillograms of water hammer produc by closing of a rapid acting slide-valve at the st of a steel pipeline suggests that cavitation bubb during the runs did not collapse simultaneous The findings of this study elucidate the physics the phenomenon and should be treated as a po of departure in detailed quantitative studies water hammer with breaks in continuity. RETROFIT OF HYDROPOWER CAPACITY AT CONEMAUGH DAM,
Villanova Univ., PA. Dept. of Civil Engineering.
R. A. Chadderton, and J. E. Niece.
Water Resources Bulletin, Vol 19, No 1, p 101-106, February, 1983. 6 Fig, 4 Tab, 4 Ref.

Descriptors: *Design criteria, *Powerplants, Turbines, Hydroelectric power, Dams, Energy, Economic aspects, Hydraulic machinery, Hydraulic equipment, *Pennsylvania, Conemaugh Dam.

Studies were conducted in the Pittsburgh District elative to the addition of hydroelectric power enerating facilities at the existing Conemaugh Dam in Pennsylvania. Selection had already been nade of 8, 10, 15 and 20 megawatt (MW) total nstalled capacities for further study. Appropriate nstallation configuration for each of these four reselected installed capacities was sought, along vith data concerning the conceptual design and ssociated cost estimates for each proposed conguration. Based on the results, the layout preerred consists of the construction of a powerhouse n a portion of the stilling basin apron to enclose nultiple Standard Tube turbines and generators. The number and size of the turbine generator units vill depend on the total installed plant capacity. The cheapest energy, on a cost per kilowatt hour asis, would be derived from a configuration inluding two Standard Tube turbines of 4 MW apacity each. The estimated construction cost for his option was about $1200 per kilowatt. Further consideration must be given to the detailed design f powerhouse roof and bearing walls so as to ssure structural adequacy under spillway dischange, anchoring of stilling basin slabs, and a nodel study for the plan. SPRING-OPERATED SEMIAUTOMATIC IRRIGATION VALVES,
Agricultural Research Service, Kimberly, ID. Snake River Conservation Research Center.
A. S. Humpherys, E. Oest, and D. A. Young.
Transactions of the ASAE, Vol 26, No 1, p 134-136, 140, 1983. 5 Fig, 6 Ref.

Descriptors: *Valves, *Mechanical equipment, *Irrigation, Pipelines, Pressure surges, Sprinkler irrigation.

Torsion spring operators for standard low pressure butterfly type irrigation valves are described. These are used with 24 hr timers to semiautomate gated pipe irrigation systems and are particularly well suited for use with flow-though single pipeine systems. They are currently marketed in 150 mm (6 in.), 200 mm (8 in.) and 250 mm (10 in.) diameter sizes. The valve is normally open and is controlled by the time so that it opens at the end of a predetermined closed time period. The valve performed well in field tests in the Grand Valley of Colorado, where it is presently being used. A valve made to operate in the reverse mode by closing when tripped was briefly tested. However, it operated similar to a check valve and closed too suddenly for most conditions. It could be used in this manner at a turnout below a supply ditch, for example, where the upstream pipe length is very short. Otherwise it could create undesirable pressure surges in the pipeline. (Baker-FRC)

PROJECT STUDIES AND RESEARCH WORK CONCERNING BUTTERFLY VALVES AS USED IN WATER POWER STATIONS AND RETARDING BASINS (PLANUNGSKRITERIEN UND FORSCHUNG BEI DROSSELKLAPPEN FUR KRAFTWERKSANLAGEN UND RUCKHALTEBECKEN),
Technische Hochschule, Darmstadt (Germany, F.R.). Fachgebiet Hydraulische Maschinen und Anlagen.
J. Osterwalder.
Wasserwirtschaft, Vol 71, No 12, p 368-372, December, 1981. 7 Fig, 1 Tab, 8 Ref.

Descriptors: *Hydroelectric plants, *Hydraulic valves, *Retarding basins, Project planning, Model testing, Valves.

Depending on the scope of application and their specifications, butterfly valves have to fulfill various requirements. Questions relating to plant security, economic aspects, and hydraulic behavior are usually of considerable importance during the planning of water power stations and retarding basins. Experimental investigations with models provide the best solutions to these questions. Although a number of publications deal with information on butterfly valves for water power stations, little information is available concerning the butterfly valves with eccentrical shutters generally used for retarding basins. Recent research in this area has included the development of model tests which enable a judgement regarding such situations in the planning phase, minimizing risks and disagreeable surprises. In many cases, necessary design modifications or changes in construction can be identified early enough to make suitable corrections. The importance of these butterfly valves in retarding basins should not be judged on the bases of their relatively low cost, but rather on the basins of the problems which may result from their failure. SMALL HYDRO FROM A SUBMERSIBLE PUMP,
Canterbury Univ., Christchurch (New Zealand). Dept. of Civil Engineering.
E. P. Giddens, W. Spittal, and D. B. Watson.
International Water Power and Dam Construction, Vol 34, No 12, p 33-35, December, 1982. 5 Fig.

Descriptors: *Pumps, *Hydroelectric power, Submersible pumps, Hydraulic machinery, Pump turbines, Generators.

A conventional submersible pump and motor, operated in the reverse mode, was tested and approved as a complete, self-contained water turbine and induction generator unit. This system is suitable for power production on the small village scale. The pump was direct-coupled to a single-phase induction motor and generated an autonomous 220V, 50 Hz single-phase supply with a system efficiency nearly the same as in the pumping mode. Improvements are planned to increase efficiency of components on scale-up and provide overspeed control. (Cassar-FRC)

LOW-HEAD WATER MILL LINKED TO CANADIAN GRID.
International Water Power and Dam Construction, Vol 34, No 12, p 76, December, 1982. 2 Fig.

Descriptors: *Turbines, *Water wheels, Hydraulic machinery, Prototypes, Prototype tests, Floats, Hydraulics, Hydraulic design, Hydroelectric power.

Electricity produced by a 6 kW floating watermill was connected to the British Columbia Hydro grid in October 1982. The mill is slung beneath a set of pontoons anchored to the river bed. Three 1.5 m long blades direct the flow. A generator is mounted on the surface. Design of the blades is especially critical because they operate on a vertical axis. The design of the 6 kW machine was based on that of a 4 kW prototype mill which had been operating in the St Lawrence for several months without problems, although the potentially most serious problem, ice, was yet to be encountered. A symmetrical hydrofoil section was selected for the blades, as it is one of the best low drag, high lift sections available. (Cassar-FRC)

FRANCIS TURBINES FOR SMALL-SCALE APPLICATIONS,
Sorumsand Verksted A/S (Norway).
N. Romcke, and J. J. Victory.
International Water Power and Dam Construction, Vol 34, No 12, p 61-65, December, 1982. 6 Fig.

Descriptors: *Turbines, Hydraulic machinery, Materials, Hydraulic design, Francis turbines, Hydraulic equipment, Hydroelectric power.

Francis turbines have been redesigned for use in small hydro schemes. The small-scale turbines use welded steel, cavitation resistant materials, and standardized components. Small units are usually arranged with a horizontal shaft. A standard but flexible design was developed to minimize costs and meet individual requirements. Twelve different models, each representing a specific speed, can be altered slightly to achieve intermediate speeds. Shaft sealing is provided by using 2 or more sealing stages drained off to the tailwater or drainage sump. No lubrication or sealing water is required. Shrinking by the oil pressure method has proven suitable for mounting the runner to the shaft. In some circumstances Francis turbines may be preferred to tubular-type turbines, especially at heads less than 20 m. (Cassar-FRC)

EROSION-CORROSION RESISTANCE OF COPPER ALLOW C72200 IN SEA WATER CONTAINING SUSPENDED SAND,
Olin Corp., New Haven, CT. Chemicals Div.
N. W. Polan, M. A. Heine, J. M. Popplewell, and C. J. Gaffoglio.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 223-231, 2 Figs, 3 Tab, 10 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Group 8G—Materials

Descriptors: *Desalination, Desalination apparatus, Distillation, *Corrosion resistance, *Copper, Copper alloy C72200.

Copper based alloys have been used frequently in salt water service in applications where thermal conductivity, fouling resistance, and good corrosion performance are required. Under conditions, such as turbulent flow or localized high velocities due to partial tube blockage, a form of accelerated attack known as erosion-corrosion can occur. Many copper base alloys, particularly the cupro nickels, are resistant to this form of attach under normal conditions. In particular, certain alloys such as C72200 have been developed specifically to resist erosion-corrosion. However, another form of erosion-corrosion is sometimes observed in locations where sand becomes entrained with the sea water, for example, in certain Middle Eastern desalting plants and European power generating plants. Previous studies have indicated that the erosion-corrosion resistant C72200 approaches the sand erosion resistant C71640. In addition, temper (and consequent hardness) has proven to be a factor. It appears likely, therefore, that at harder tempers, C72200 may equal or exceed the sand erosion resistance of C71640. Coupled with the excellent erosion-corrosion of the alloy and lower cost due to a much lower nickel content, this new alloy may be an attractive candidate for desalting and heat exchanger use where sand entrainment is a problem.

CORROSION PROBLEMS CAUSED BY BROMINE FORMATION IN MSF DESALINATION PLANTS,
INCO Europe Ltd., Birmingham (England).
J. W. Oldfield, and B. Todd.
In: Desalination, Vol 38, Nos 1/2/3, November 1981. p 233-245, 7 Fig, 25 Ref (1st Vol of the Proc of the Intern Congress on Desalination and Water Reuse, Bahrain, Nov 29-Dec 3, 1981).

Descriptors: *Desalination, Desalination plants, *Corrosion, Multistage flash distillation, , Chlorination, Hydrogen ion concentration, Bromine.

The chlorination of sea water has been considered in detail, with particular reference to the oxidation of bromide ions, already present in sea water, to bromine by the chlorine. Under normal conditions of sea water chlorination, bromide ions will rapidly be oxidized to bromine, hypobromous acid and hypobromite ion, bromine being the predominant form at pH values of 6 and less. The significance of this work to MSF desalination plants is that acid treated plants provide conditions suitable for bromine gas formation in the decarbonator and deaerator. For such plants operating with residual chlorine levels in the range 0.2 to 0.5 ppm the condensates from the steam that has passed through the deaerator into the vent system could well contain between 10-100 ppm Br2; these levels of bromine can cause severe localized corrosion problems with conventional stainless steels. Such corrosion has been observed in practice. Calculations indicate that providing the pH is 6 and the residual chlorine is less than 0.22 ppm at the point of entry to the deaerator, the likely bromine level in the condensate in the vent system will be less than 10 ppm, and this may well be low enough to prevent corrosion of type 316 stainless steel.

STUDIES OF THE LOCALISED-CORROSION BEHAVIOUR OF SOME STAINLESS STEELS, INCOLOY 825 AND TITANIUM IN SEAWATER,
Glasgow Univ. (Scotland). Dept. of Mechanical Engineering.
T. Hodgkiess, and A. Asimakopoulos.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 247-256, 4 Figs, 3 Tables, 11 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Distillation, *Corrosion, Multistage flash distillation, Titanium, Chromium.

The localised-corrosion behaviour of several high-grade materials has been investigated in a range of conditions of relevance to desalination plant. Under the conditions studied, no evidence has been found of pitting, crevice corrosion or stress-corrosion cracking in titanium. The remaining materials, all chromium-containing, have exhibited similar immunity as titanium in the least aggressive environments but, to an extent depending upon the material and conditions, they have been found to be susceptible to pitting and crevice corrosion in the more severe conditions featured in this work. The relevance of the observations to distillation-plant operation is discussed.

ACID CLEANING AND PASSIVATION OF POWER PLANT CONDENSERS AND DESALINATION PLANTS,
Rome Univ. (Italy). Ist. di Chimica Applicata ed Industriale.
R. Cigna, A. de Maio, L. Giuliani, and G. Gusmano.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 269-279, 8 Fig, 4 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Cleaning, Corrosion control, Powerplants, *Tubes, Copper, Alloys.

Acid cleaning and passivation treatments of copper alloy tubes are described. The suitability of corrosion monitoring to follow each step of such operation is demonstrated. To regenerate a clean surface on copper alloy tubes after improper conservation or after corrosive conditions during service, an acid cleaning and pre-passivation treatment has proven to be a very useful and industrially viable method. Such a treatment has definite advantages over any mechanical cleaning method as far as complete dissolution of corrosion products with deterioration of the metallic surface is concerned. The pre-passivation protects the exposed surface in case of further conservation and/or descreases surface reactivity during start-up, thereby allowing a uniform growth of corrosion layers. In case of pitting corrosion, the presence of a Cu-BTA salt film acting as a cathodic inhibitor minimizes any impingement attack which could be provided locally by the pitting morphology.
W84-00231

QUALITY CONTROL PROBLEMS IN COPPER ALLOY TUBES MANUFACTURING,
Rome Univ. (Italy). Ist. di Chimica Applicata ed Industriale.
G. Gusmano, and G. Dall'Omo.
In: Desalination, Vol 38, Nos 1/2/3, November 1981, p 281-293, 16 Fig, 4 Ref. (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Bahrain, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination apparatus, *Corrosion, Copper alloy, *Condenser tubes, Tube integrity.

The quality control of copper alloy condenser tubes cannot be limited to mechanical characteristics, microstructure and chemical composition, but should be extended to cover such not yet fully standardized topics as tube integrity and surface conditions. An analysis of possible defects, with particular regard to internal ones and their relevance of tube life is given together with their causes. Problems related to detection of internal defects by means of eddy current test are also discussed.
W84-00232

PRE-SERVICE CORROSION CONTROL IN MULTIFLASH DESALINATION PLANTS,
Atel SRL, Rome (Italy).
L. Giuliani.
In: Desalination, Vol 38, 1/2/3, November 1981, p 295 (Abstract only) (1st. Vol of the Proc. of the Intern. Congress on Desalination and Water Reuse, Nov. 29-Dec. 3, 1981, Bahrain).

Descriptors: *Desalination, Desalination plants, *Multistage flash, *Corrosion control, Preconditioning treatment, Stainless steel, Copper alloys.

Multiflash desalination plants are characterized by large heat exchange surfaces and presence of noble alloys which might be sensitive to localized corrosion attack during manufacturing, transportation and commissioning. To avoid premature failure, all surfaces must be preserved clean and free from corrosion nucleation until the plant starts its normal operation. A detailed analysis is given of possible corrosion causes and available remedies. Some Pre-conditioning treatments are outlined, especially for stainless steel and copper alloys.

8I. Fisheries Engineering

STUDY OF FISH MANAGEMENT AT THE LG 2 RESERVOIR (TRAVAUX D'AMENAGEMENT PISCICOLE AU RESERVOIR DE LG 2),
Societe d'Energie de la Baie James, Montreal (Quebec).
N. Faubert.
Canadian Water Resources Journal, Vol 7, No 2, p 172-180, 1982. 2 Fig, 2 Ref.

Descriptors: *Reservoirs, *Fisheries management, Reservoir fisheries, Fish populations, Reservoir construction, Reservoir design, Water level fluctuations, James Bay, La Grande Complex, Canada.

In order to determine the likelihood for future reservoirs in the La Grand Complex in northern Canada to be naturally populated by certain species of fish, the Societe d'energie de la Baie James decided to perform a fish management program before the reservoirs are impounded. The program involves deforestation and cleaning of the mouths of some tributaries and littoral sections, which exposes the surface materials more quickly, while preventing the accumulation of ligneous material and the resulting clogging. Building retaining dikes in small bays, such as dike BA-02 at reservoir LG 2, has made it possible to eliminate the effects of fluctuating water levels in the reservoir. In addition, the removal of obstructions from river courses and the creation of fish ways facilitates the movements of fish to sites where they will spawn or feed. (Author's abstract)

A Comment on the Paper by John R. M. Kelso and Gary S. Milburn: 'Entrainment and Impingment of Fish by Power Plants in the Great Lakes Which Use the Once-Through Cooling Process, (J. Great Lakes Res. 5:182-194, 1979),
W84-00019 6G

FISH POPULATIONS
The Effects of Low Level Turbidity on Fish and Their Habitat,
W84-00162 5C

FISHERIES MANAGEMENT
Study of Fish Management at the LG 2 Reservoir (Travaux D'Amenagement Piscicole Au Reservoir De LG 2),
W84-00318 8I

FJORDS
A Numerical Model of Circulation in a Continental Shelf-Silled Fjord Coupled System,
W84-00298 2L

FLOOD CONTROL
Aspen Clearcutting Increases Snowmelt and Storm Flow Peaks in North Central Minnesota,
W84-00103 4C

FLOOD PLAINS
The Impact of Floodplain Regulations on Residential Land Values in Oregon,
W84-00089 6F

A Small-Scale Flood Plain,
W84-00189 2J

FLOOD ROUTING
Runoff Model for Watersheds of Nonhomogeneous Hydrologic Characteristics,
W84-00137 2A

Comment on 'Optimal Risk-Based Design o Flood Levee Systems' by Y.-K. Tung and L. W Mays,
W84-00350 2E

FLORIDA
Impacts of Silviculture on Flatwoods Runoff Water Quality, and Nutrient Budgets,
W84-00101 4C

FLOW MEASUREMENT
Measurement of the Performance of Sewerage Systems and Associated Hydraulic Structures-Recent Developments,
W84-00092 5D

FLOW REGULATION
Asymptotic Distribution of the Maximum Deficit with Correlated, Partially Regulated Outflows,
W84-00107 4A

FLUID MECHANICS
Water Hammer with Breaks in the Continuity o the Liquid,
W84-00311 8E

FLUIDIZED BEDS
Anaerobic Fluidized Bed Experimentation with a Molasses Wastewater,
W84-00173 5D

FLY ASH
Cellular Bioassay of Fish as a Sensitive Index o Water Quality Related to Ash From Coal Combustion,
W84-00009 5C

FOAM CONTROL ADDITIVES
Foam Control Additives in MSF Desalination
W84-00220 3A

FOOD CHAINS
Food Chain Enrichment of Organochlorine Compounds and Mercury in Clean and Polluted Lakes of Finland,
W84-00023 5E

Accumulation of Cadmium in a Freshwater Food Chain Experimental Model,
W84-00074 5C

Production of Filter-Feeding Trichoptera in an Impounded and a Free-Flowing River,
W84-00079 6G

Selective Feeding by Zooplankton: Implications for Lake Productivity,
W84-00165 2H

FOOD HABITS
Seasonal Cycles of Zooplankton and Related Phytoplankton Development in Three Shallow Mesotrophic Lakes in Northern Canada,
W84-00305 2H

FOREST MANAGEMENT
Climatological Watershed Calibration,
W84-00095 4D

A Decision Model to Predict Sediment Yield From Forest Practices,
W84-00099 4C

Impacts of Silviculture on Flatwoods Runoff Water Quality, and Nutrient Budgets,
W84-00101 4C

FOREST WATERSHED
Modeling Surface and Subsurface Stormflow on Steeply-Sloping Forested Watersheds,
W84-00032 4D

FOREST WATERSHEDS
The Use of Strontium-87/Strontium-86 Ratios to Measure Atmospheric Transport Into Forested Watersheds,
W84-00176 5B

FORESTRY
Aspen Clearcutting Increases Snowmelt and Storm Flow Peaks in North Central Minnesota,
W84-00103 4C

FOULING
Transient Kinetics of Processes at Membrane/Solution Interfaces,
W84-00160 3A

FRANCE
Impact of Pollution on Zooplankton Communities in the Marseilles Domestic Sewage Discharge Zone. (Impact De La Pollution Sur Les Communautes Zooplanctoniques Dans La Zone D'Epandage De L'Emissaire Urbain De Marseille),
W84-00157 5C

FRICTION
Extremal Hypotheses for River Behavior,
W84-00129 2E

FUEL
Options for Handling Stillage Waste From Sugar-Based Fuels Ethanol Production,
W84-00330 5B

GEOGRAPHY
Geoprocessing - A Water Distribution Management Tool,
W84-00196 7C

GEOHYDROLOGY
Integrating a Ground Water Data Reconnaissance Program Into a Mineral Exploration Program,
W84-00096 7A

Water Balance of the Black Sea in the Late Valdai Glacial Epoch,
W84-00332 2A

Estimation of the Volume of Regenerated Water of the Continental Crust in Global Water Exchange,
W84-00345 2A

Interrelationship between Relief, Global Climate, and Water Exchange,
W84-00346 2A

GEOPHYSICAL EXPLORATION
Geophyiscal Exploration Surveys for Ground Water in the San Pedro Basin, Arizona,
W84-00007 3B

GEOPROCESSING
Geoprocessing - A Water Distribution Management Tool,
W84-00196 7C

GEORGIA
Legal Aspects of Water Resources: A Survey of the Law in Georgia,
W84-00008 6E

A Decision Model to Predict Sediment Yield From Forest Practices,
W84-00099 4C

Construction of an Integrated and Economically Efficient Water Allocaion Process for the Flint River,
W84-00199 6A

Water Resources Organizations in Georgia,

GEOTHERMAL STUDIES
Heat Transfer in Fractured Geothermal Reservoirs with Boiling,
W84-00086 2F

Desalination Plant Using Low Grade Geothermal Heat,
W84-00268 3A

GOVERNMENT AGENCIES
Water Resources Organizations in Georgia,
W84-00202 6E

GRAVITY STUDIES
Geophyiscal Exploration Surveys for Ground Water in the San Pedro Basin, Arizona,
W84-00007 3B

GROUNDWATER
Geophyiscal Exploration Surveys for Ground Water in the San Pedro Basin, Arizona,
W84-00007 3B

Tapping Ground Water for Heating and Cooling,
W84-00024 8C

Maximum Application Rates for Land Treatment of Septage,
W84-00040 5E

Mineral Precipitation in North Slope River Icings,
W84-00301 2K

Groundwater-Solute Influx,
W84-00303 2L

GROUNDWATER MANAGEMENT
An Eigenvalue Numerical Technique for Solving Unsteady Linear Groundwater Models Continuously in Time,
W84-00083 2F

GROUNDWATER MOVEMENT
An Eigenvalue Numerical Technique for Solving Unsteady Linear Groundwater Models Continuously in Time,
W84-00083 2F

A Numerical Procedure for the Solution of the Steady State Variable Density Groundwater Flow Equation,
W84-00087 2F

Simulation of Salt Water-Fresh Water Interface Motion,
W84-00116 2F

An Evaluation of Selected Halocarbons and Trace Gases for Potential Use as Indicators of Groundwater Movement and Source (and Contaminant Movement in the Vadose Zone),
W84-00201 5B

The Water-Table of the Rhine Plain in Alsace (La Nappe Phreatique De La Plaine Du Rhin En Alsace),
W84-00314 2F

GROUNDWATER POLLUTION
Groundwater Monitoring at a Septage Lagoon Facility,
W84-00002 5B

A Test of the Water and Land Resource Analysis System in the New Jersey Pine Barrens,
W84-00044 5G

How the Rocky Mountain Arsenal Is Handling Groundwater Contamination,
W84-00133 5D

An Evaluation of Selected Halocarbons and Trace Gases for Potential Use as Indicators of Groundwater Movement and Source (and Contaminant Movement in the Vadose Zone),
W84-00201 5B

The Water-Table of the Rhine Plain in Alsace (La Nappe Phreatique De La Plaine Du Rhin En Alsace),
W84-00314 2F

Evaluation of Nitrogen and Irrigation Management for Corn Production Using Water High in Nitrate,
W84-00344 5B

GUAYULE
Assessing Brackish Water for Guayule Rubber Production,
W84-00139 3C

HABITAT RECOVERY
Recovery Patterns in Stream Communities Impacted by the Mt. St. Helens Eruption,
W84-00039 5C

HALOPHYTE
Optimization of Primary Production by the Halophytic Alga, Dunaliella Salina, In Saline Water,
W84-00138 3C

HEAT EXCHANGE
Hydrodynamics and Heat Exchange During Film Evaporation of Sea Water in a Vapour-Water Upflow,
W84-00064 3A

HEAT RECOVERY
Industrial Water Reuse Versus Net Water Loss,
W84-00042 3E

HEAT TRANSFER
Final report on the Testing of the Absorption Freezing Vapor Compression Pilot Plant at the Wrightsville Beach Test Facility,
W84-00001 3A

Heat Transfer in Fractured Geothermal Reservoirs with Boiling,
W84-00086 2F

HEAT TRANSFER SURFACES
The Effect of Air on Condensation on a Roped Tube,
W84-00210 3A

HEATING
Tapping Ground Water for Heating and Cooling,
W84-00024 8C

HEAVY METALS
The Application of Kaolin for Control of Heavy Metals in Anaerobic Sludge Digestion,
W84-00003 5D

The Induction of Tolerance to Heavy Metals in Natural and Laboratory Populations of Fish,
W84-00035 5C

Metal Loading of the B. Everett Jordan Reservoir,
W84-00051 5B

Abatement of Heavy Metals in Industrial Effluents by a Catalyzed, Electrochemical Removal Scheme,
W84-00161 5D

Trace Metal Contamination of Shallow Marine Sediments Near a Lead Smelter, Spencer Gulf, South Australia,
W84-00312 5B

Accumulation of Heavy Metals in Unicellular Algae,
W84-00331 5B

Simultaneous Determination of Heavy Metals in Waters by Inductively-Coupled Plasma Atomic Emission Spectrometry After Extraction Into Diisobutyl Ketone,
W84-00334 5A

Trace Metal Determinations in Estuarine Waters by Electrothermal Atomic Absorption Spectrometry after Extraction of Dithiocarbamate Complexes into Freon,
W84-00347 5A

HERBICIDES
Degradation of Atrazine in Estuarine Water/Sediment Systems and Soils,
W84-00018 5B

Herbicides in Runoff from Agricultural Watersheds in a High-Winter-Rainfall Zone,
W84-00037 5B

HEURISTIC SOLUTION
A Heuristic Solution Procedure for a Joint Reservoir Control-Capacity Expansion Problem,
W84-00106 4A

HYDRAULIC LOSS
Bend Losses in Drop Inlet Spillways,
W84-00090 8B

HYDRAULIC VALVES
Project Studies and Research Work Concerning Butterfly Valves as Used in Water Power Stations and Retarding Basins (Planungskriterien Und Forschung Bei Drosselklappen Fur Kraftwerksanlagen Und Ruckhaltebecken),
W84-00313 8C

HYDROELECTRIC PLANTS
Evaluation of the Economic Efficiency of the Operation of a Hydroelectric Station on the Basis of Specific Water Discharges,
W84-00142 8A

Project Studies and Research Work Concerning Butterfly Valves as Used in Water Power Stations and Retarding Basins (Planungskriterien Und Forschung Bei Drosselklappen Fur Kraftwerksanlagen Und Ruckhaltebecken),
W84-00313 8C

HYDROELECTRIC POWER
Small Hydro From a Submersible Pump,
W84-00320 8C

HYDROGEN ION CONCENTRATION
Effect of Low pH on the Chemical Composition of Aquatic Invertebrates from Tundra Ponds at the Smoking Hills, N.W.T., Canada,
W84-00073 2H

Taranto Desalination Plant: A Comparison Between Theoretical and Actual pH Values in a Correct Design Acid Treatment Plant,
W84-00223 3A

HYDROGRAPH ANALYSIS
Hydrogeology (Hydrogeologie),

SELECTED WATER RESOURCES ABSTRACTS

VOLUME 17, NUMBER 2
FEBRUARY 1984

51 -- W84-00700
SWRABW

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 421, Reston, VA 22092, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are:
Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 17, NUMBER 2
FEBRUARY 1984

W84-00351 – W84-00700

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Office of Management ond Budget through September 30, 1985.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientitsts, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

WATER CYCLE

General

CUSSION: ASPECTS OF HYDROLOGY IN PROVINCE OF NORTH SUMATRA, ONESIA,
ld, and J. K. Hall.
eedings of the Institution of Civil Engineers, 2: Research and Theory, Vol 73, No 4, p 829-December, 1982. 1 Fig, 2 Tab, 14 Ref.

riptors: *Hydrology, *Runoff, Sumatra, Indo-, Climatic data, Rainfall-runoff relationships, ydrology, River flow, Evapotranspiration, ds, Groundwater.

above titled paper, published in Proceedings ie Institution of Civil Engineers, Part 2, me 73, pages 85-108, March 1982, prompted a nent by J. R. Wood and M. J. Hall about the ology of West Sumatra. North and West Su-a are similar in physical geography and have ir hydrometric networks. However, climatic neters vary widely in space, time, and degree. Sumatra has an average annual rainfall of + or - 714 mm. Drought can occur in June July. R. B. Bulman raised several questions relationships derived from the rainfall and f data. The authors replied to the comments, g that river flows are governed by the geo-nature of the basins, which are recent volcan-ixed volcanic, old volcanic, and sediments. nt volcanic soil deposits have the greatest ration rates and the least runoff. E OF GLACIERS IN WATER EXCHANGE HE USSR,
. Krenke.
r Resources (English Translation), Vol 9, No 254-262, May-June, 1982. 2 Fig, 2 Tab, 26 Ref. slated from Vodnye Resursy, No 3, p 47-56, June, 1982.

riptors: *Hydrologic cycle, *Glacier mass bal-, *Water exchange, *Runoff, USSR, Basins, ns, Artic Ocean, Caspian Sea, Azov Sea, k Sea, Bering Sea, Water levels, Water supply, pitation, Advection.

The completion of cataloging of the glaciers of the USSR and the development of a method for estimating the average depth of accumulation of moisture in glacial systems will make it possible to evaluate the role of glaciation in water exchange in the USSR. The total mass of USSR glaciers, equal to the volume of water being held in them, is estimated by indirect calculations made by various methods and using available geophysical data at 17,000 billion metric tons, i.e., 17,000 cu km. The 25 cu km of moisture annually accumulated by mountain glaciation and the 12 cu km entering the delayed ice cycle are very small quantities by comparison. Glaciation plays a slightly greater role in the moisture cycle of the mountainous part of Central Asia. Here the resultant advection of moisture to a territory of 485,000 sq km is equal annually to about 520 cu km, and the outflow is 400 cu km. When examining glacial runoff and its significance for the water balance in large basins it is noted that the Arctic Ocean receives 26 cu km of water annually from the insular ice caps. More than 2 cu km of glacial water is delivered to this ocean by rivers. In the runoff of rivers to the Bering Sea and the open part of the Pacific Ocean glacial waters amount to 0.8%, and in the runoff to the Okhotsk Sea to only 0.1%. The Azov and Black Seas annually receive from the USSR territory 1.93 cu km of glacial waters, which is apparently equal to half of the glacial waters in these areas. The Caspian Sea receives 1.23 cu km of glacial waters from the Caucasus, or 0.4% of the total runoff to this sea. The only large basin in the USSR where the role of glacial waters in the structure of the annual water balance is quite noticeable is the basin of the Aral Sea. (Baker-FRC)

THE WORLD OCEAN AND ITS ROLE IN PLANETARY MOISTURE, HEAT, AND SALT EXCHANGE,
V. N. Stepanov.
Water Resources (English Translation), Vol 9, No 3, p 217-237, May-June, 1982. 4 Fig, 10 Tab, 39 Ref. Translated from Vodnye Resursy, No 3, p 4-28, May-June, 1982.

Descriptors: *Oceans, *Ocean circulation, *Water exchange, *Hydrologic budget, *Salinity, Salts, Evaporation, Runoff, Continental runoff, Ocean climates.

The Concept of the hydrosphere as a unified envelope of the earth is valid only in that the waters of the planet are linked by a global cycle. In regions where evaporation predominates over the amount of precipitation an increase in salinity of the surface waters of the ocean occurs; salinity convection develops, causing stratification and many other characteristics of the oceanosphere at low latitudes. At the same time the air is saturated with water vapor which is carried landward, due to which the surplus wetting of tropical territories occurs. Moisture exchange is directly related to salt exchange; this pertains not only to the oceanosphere and atmosphere, but also to land waters. During the action of wind waves, spraying of water occurs, leading to the ejection of salts into the atmosphere. Consideration is also given in this review to the distribution of water and land and the size of oceans, the areas and volumes of waters within the main morphological parts of the ocean bottom, the volumes of characteristic water layers, the exchange of energy and materials and planetary processes, solar energy and its role in global mass transport and redistribution, the cyclic nature of development of planetary processes, moisture exchange of the world ocean and the global hydrologic cycle, evaporation, precipitation, continental runoff, moisture budget of the world ocean surface, freshwater balance in the world ocean, heat exchange of the world ocean and its relation to planetary heat and moisture exchange, absorbed solar radiation, expenditure of heat on evaporation, turbulent heat exchange with the atmosphere, heat balance of oceans, estimations of the exchange of salts of the world ocean with the atmosphere and land, components of salt exchange through the ocean surface, and salt exchange between ocean and land. (Baker-FRC)
W84-00382

EVALUATION OF MAXIMUM LIKELIHOOD PARAMETER ESTIMATION TECHNIQUES FOR CONCEPTUAL RAINFALL-RUNOFF MODELS: INFLUENCE OF CALIBRATION DATA VARIABILITY AND LENGTH OF MODEL CREDIBILITY,
Case Western Reserve Univ., Cleveland, OH.
S. Sorooshian, V. K. Gupta, and J. L. Fulton.
Water Resources Research, Vol 19, No 1, p 251-259, February, 1983. 5 Fig, 5 Tab, 24 Ref.

Descriptors: *Rainfall-runoff relationships, *Model studies, *Calibrations, Maximum likelihood estimates, Leaf River, Mississippi, Streamflow, Runoff, Error analysis.

The performances of two maximum likelihood estimators were compared with the simple least squares (SLS) criterion using the soil moisture accounting model of the U.S. National Weather Service's River Forecast System (SMA-NWSRFS). Data from the Leaf River Basin, Mississippi, included 18 years of precipitation, daily potential evapotranspiration estimates, and mean daily streamflow discharge rates. The maximum likelihood estimators were AMLE, which assumes the presence of first lag autocorrelated homogeneous variance errors, and HMLE, which assumes the presence of uncorrelated inhomogeneous variance errors. HMLE provided more realistic parameter estimates and more reliable forecasts and was less affected by the nature and length of data used for calibration. The SLS and AMLE, similar to each other in performance, were quite sensitive to variability and length of data. (Cassar-FRC)
W84-00397

AUTOMATIC CALIBRATION OF CONCEPTUAL RAINFALL-RUNOFF MODELS: THE QUESTION OF PARAMETER OBSERVABILITY AND UNIQUENESS,
Case Western Reserve Univ., Cleveland, OH.
S. Sorooshian, and V. K. Gupta.
Water Resources Research, Vol 19, No 1, p 260-268, February, 1983. 8 Fig, 1 Tab, 19 Ref.

Descriptors: *Rainfall-runoff relationships, *Model studies, *Calibrations, Maximum likelihood estimates, Leaf River, Mississippi, Streamflow, Runoff, Error analysis.

Problems in automatic calibration of conceptual rainfall-runoff models are reviewed. The most important of these problems is an inability to obtain unique and conceptually realistic parameter sets because of poor properties of the response surface. Most models cannot be properly identified even with synthetic data because of inadequacies in the model structure and in the automatic techniques used for calibration. An analysis of the SMA-NWSRDS model using the simple least squares criterion and the HMLE maximum likelihood estimator showed that the latter greatly improved the parameter estimates obtained through calibration because it has the ability to recognize and account for heteroscedasticity in the residuals. (Cassar-FRC)
W84-00398

UNIQUENESS AND OBSERVABILITY OF CONCEPTUAL RAINFALL-RUNOFF MODEL PARAMETERS: THE PERCOLATION PROCESS EXAMINED,
Case Western Reserve Univ., Cleveland, OH. Dept. of Systems Engineering.
V. K. Gupta, and S. Sorooshian.
Water Resources Research, Vol 19, No 1, p 269-276, February, 1983. 8 Fig, 1 Tab, 12 Ref.

Descriptors: *Rainfall-runoff relationships, *Model studies, *Calibrations, Runoff, Streamflow, Percolation, Infiltration, Error analysis.

The failure to obtain unique estimates for the parameters of conceptual rainfall-runoff models can be partly corrected by appropriate reparameterizations of the pertinent model equations. This was done for the percolation equation of the National Weather Service River Forecast System model. A unique optimum parameter set was observed without having affected the original behavior of the

model or altering the conceptual realism of the parameters. These results may be extended to other models and to other structures within the models which cause problems in calibration. (Cassar-FRC)

PREDICTIVE MODELS FOR ESTIMATING NET RAINFALL AND INTERCEPTION LOSSES IN SAVANNA VEGETATION,
Durban-Westville Univ. (South Africa). Dept. of Geography.
G. Du T. De Villiers.
Water SA, Vol 8, No 4, p 208-212, 1982. 5 Fig, 7 Tab, 16 Ref.

Descriptors: *Model studies, *Rainfall, *Interception, Water loss, Savanna, Vegetation.

Predictive models have been formulated from existing savanna interception data. While interception experimental plot results vary, research indicates that similarities do exist. Independent plot results therefore should be able to be grouped together for application on a regional basis. Throughfall measurements were surprisingly similar under different canopy conditions. Stemflow, highly variable in savanna vegetation covers, is nevertheless predictable from gross rainfall records, and although the average stemflow per storm is often less than 5% of the gross rainfall, it represents a concentrated application of water to soil at a point where conditions are ideal for entry. Sufficient water is added to the soil to cause wetting to considerable depth. For the storms that have been investigated, interception losses for savanna vegetation vary in most cases between 15 and 20% of the gross rainfall, which is far from an insignificant quantity of water. The evaporation rate and the rainfall rate are primary variables influencing this loss. Interception losses in savanna vegetation are not greatly affected by a variety of canopy conditions. Data concerning the rainfall characteristics and the evaporation rate of essential for an accurate estimation of interception losses. (Baker-FRC)

DESIGN RAINFALL DISTRIBUTIONS FOR THE STATE OF WYOMING,
Wyoming Univ., Laramie. Dept. of Civil Engineering.
P. T. Tyrrell, and V. R. Hasfurther.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-132513, Price codes: A03 in paper copy, A01 in microfiche. Water Research Center Completion Report, August 1983. 41 p, 4 Fig, 11 Tab, 26 Ref. OWRT A-036-WYO(1), 14-34-0001-2154.

Descriptors: Rainfall-runoff relationships, *Rainfall distribution, Hyetographs, Flood frequency, Synthetic hydrology, Parametric hydrology, *Flood forecasting, *Design storms, *Wyoming.

Design storm patterns for use in predicting floods by simulating precipitation events in ungaged drainage basins in Wyoming are presented. The design patterns were developed from observed rainfall and are separated into two categories: thunderstorms (events less than four hours in duration) and general storms (events lasting four or more hours). Comparisons of predicted runoff using the new design storms and design storms recommended by the U.S. Soil Conservation Service and the Bureau of Reclamation were made using HEC-1, HYMO, and SCS Triangular Hydrograph and U.S.G.S. distributed routing digital rainfall-runoff models. The new design storms typically produce greater runoff peaks when simulating thunderstorm events, and smaller peaks when simulating runoff from general storms, than those predicted with the established procedures. Instructions describing the use and limitations of the new storm pattern construction method are included.

2B. Precipitation

SELECTED CLIMATIC CHARACTERISTICS OF THE SOUTHEASTERN UINTA BASIN, UTAH AND COLORADO,
Geological Survey, Salt Lake City, UT. Water Resources Div.
S. D. Waltemeyer.
USGS Open-File Report 82-91 (WRI), 1982. 33 p, 22 Fig, 5 Tab, 20 Ref.

Descriptors: *Hydrologic data, *Climatic data, *Regional analysis, *Networks, Monitoring, Oil shale, Precipitation, Air temperature, Evaporation, *Utah, *Colorado, Uinta Basin.

The southeastern Uinta Basin in Utah and Colorado contains large reserves of oil shale, the mining of which could affect the area's water resources. Climatic characteristics of the area, which were evaluated as one phase of a comprehensive hydrologic study, are presented to help provide the means of evaluating the impact of mining on the area's water resources. Data for precipitation, air temperature, and evaporation obtained by the U.S. Geological Survey from October 1974 to September 1978, and similar short-term data obtained by other Federal agencies at sites in and near study area, were tabulated and adjusted to a 19 70 base period. For all sites with incompl records for 1941-70, the data were adjusted relating them to concurrent data collected at c or more long-term National Oceanic and Atm spheric Administration sites. Maps were prepa showing areal variance for normal annual preci tation, normal annual air temperature, and norr annual pan evaporation.. The normal annual p cipitation ranges from less than 8 inches for a tudes under 5,000 feet to more than 20 incl above 9,000 feet. The normal annual air tempe ture ranges from 37 to 47 degrees Fahrenheit a varies inversely with altitude and latitude. T normal annual pan evaporation ranges from 42 60 inches and varies directly with normal ann air temperature. Although not mapped, it is sho that the normal April 1 water content of the sno pack increases from about 5 inches at 7,000 feet about 11 inches at 9,000 feet. In addition, the ye to-year and within-year variances of some clima characteristics are illustrated. The standard er of estimate when relating normal annual precipi tion to altitude is 17%, which is equivalent to t standard error when relating the average for years of observed record at a site to the long-te mean at the site. Thus, it appears that additio observation points would not improve areal cov age unless the observation sites were continued f 5 years or longer. (USGS)

2C. Snow, Ice, and Frost

DOWNWARD WATER MOVEMENT IN FROZEN GROUND, WESTERN ARCT COAST, CANADA,
British Columbia Univ., Vancouver. Dept. of G ography.
J. R. Mackay.
Canadian Journal of Earth Sciences, Vol 20, No p 120-134, 1982. 11 Fig, 1 Tab, 93 Ref.

Descriptors: *Thawing, *Permafrost, *Hydrolog budget, Melting, Frozen ground, Canada, Arc zone.

Field and laboratory evidence is presented whi shows that in summer water can move downwar into the frozen active layer and subjacent perm frost in response to both thermodynamic a gravitational potentials arising during freeze-tha processes. Direct field evidence discussed includ data from drilling and neutron probe loggin which shows a summer increase in the ice conte of the subjacent frozen ground caused by sno melt infiltration in both permafrost and non-perm frost areas. Conditions which favor the downwa migration of water from thawed to frozen grou are examined in terms of thermally induced h draulic gradients, hydraulic conductivity, conte of unfrozen pore water, temperature gradients, i content, and gravity. Some geocryologic implic tions of the summer growth of ice in frozen grou include the effects on water balance calculatio the origin of patterned ground, the acceleration warming of the layer and the top of permafrost, net downslope frost creep component, and upward loss in winter at sites where water regula ly migrates into the top of the permafrost summer. SIMULATED STREAMFLOW DATA FOR NORTH CAROLINA,
North Carolina State Univ. at Raleigh. Dept. of Biological and Agricultural Engineering.
E. H. Wiser.
UNC-WRRI Rpt. No 170, December 1981. 41 p, 3 Fig, 6 Ref, 11 Append. OWRT A-093-NC(1), 14-34-0001-7070.

Descriptors: *Streamflow forecasting, Simulation analysis, Simulation, Streamflow, *Water data, Mean flow, Low flow, High flow, Watersheds, *North Carolina, Synthesis, Reservoir regulation.

A system was developed for simulation of streamflow data at any point in a region. The system is know as NCSSARR(North Carolina version of the Streamflow Synthesis and Reservoir Regulation model). NCSSARR is based on the Streamflow Synthesis and Reservoir Regulation (SSARR) Program developed at the North Pacific Division of the Corps of Engineers in Portland, Oregon. Control programming minimizes input requirements to permit a planner with limited hydrologic or computer background to use the system. The system is interfaced with the data storage and retrieval system known as HISARS to provide convenient data access as well as routine processing of the simulated streamflow data. Simulated streamflow data have been obtained for most river basins in North Carolina. Parameters required for the simulation have been obtained by comparing the simulated data with observed data wherever available. After fitting, the simulated data have been compared with observed data with respect to several criteria, including mean flow, low flow, high flow and monthly distribution. The data are in reasonable agreement for most stream gages, implying that the simulated data may be used in lieu of observation wherever the latter are not available.

LINEAR THEORY OF SUBSURFACE STORM FLOW,
Vanderbilt Univ., Nashville, TN. Dept. of Civil and Environmental Engineering.
A. D. Koussis, and L. -T. Lien.
Water Resources Research, Vol 18, No 6, p 1738-1740, December, 1982. 1 Fig, 1 Tab, 4 Ref.

Descriptors: *Mathematical equations, *Streamflow, *Kinematic wave theory, *Mathematical studies, *Hydrographs, *Storm seepage, Mathematical models, Storm runoff, Surface runoff, Surface flow, Subsurface drainage, Infiltration, Permeability coefficient.

A solution to the subsurface storm flow problem, a special case of the interflow problem connected to streamflow, is developed through linearization of the complete one-dimensional governing equation. Water surface profiles and outflow hydrographs obtained from this mathematical approximation are compared with the exact solution and with the kinematic approximation to this problem for cases in which subsurface storm flow is equated to four times the product of the constant infiltration intensity and the cosine of the bedrock inclination divided by the product of the hydraulic conductivity and the square of the sine of the bedrock inclination. The accuracy and range of applicability of the proposed theory are greater than that of the kinematic theory, and its results are considered satisfactory for cases where the subsurface storm flow is greater than or equal to 0.25 and less than or equal to 1. LOW-FLOW CHARACTERISTICS OF STREAMS IN THE LAKE MICHIGAN BASIN, WISCONSIN,
Geological Survey, Madison, WI. Water Resources Div.
B. K. Holmstrom.
USGS Open-File Report 81-1193 (WRI), March 1982. 102 p, 7 Fig, 2 Plates, 3 Tab, 18 Ref.

Descriptors: *Low flow, *Streamflow, *Streamflow forecasting, *Regression analysis, Low-flow frequency, Equations, Baseflow, Evaluation, Flow characteristics, Flow duration, Flow rates, *Wisconsin, Lake Michigan basin.

Low-flow characteristics of streams in the Lake Michigan basin are presented. Included are estimates of low-flow frequency at 30 gaging stations, flow duration at 13 gaging stations, and selected low-flow frequency characteristics at 22 low-flow partial-record stations and 123 miscellaneous sites. Equations are provided to estimate low-flow characteristics at sites where one base-flow discharge measurement is available. The equations were determined from multiple-regression analyses that related low-flow characteristics at gaging stations and low-flow partial-record stations to basin characteristics. Drainage area and base-flow index were the most significant characteristics in explaining the variation in low flow for sites where one low base-flow measurement (flow durations greater than 80%) has been made. The equations and corresponding standard errors of estimate are computed. Low-flow characteristics are not well defined in the Lake Michigan basin. Standard errors for low-flow characteristics at gaging stations, low-flow partial-record stations, and miscellaneous sites are much higher than State averages. The standard errors for the regression equations are also very high. This is due in part to the flow of many streams in the basin approaching 0 ft/s during low base-flow periods. The graphical regression relation lines are steep for stations on these streams and the resulting standard errors are relatively high. (USGS).

THE INHERENT ASYMMETRY OF RIVER MEANDER PLANFORM,
McGill Univ., Montreal (Quebec). Dept. of Geography.
M. A. Carson, and M. F. Lapointe.
Journal of Geology, Vol 91, No 1, p 41-55, 1983. 15 Fig, 3 Tab, 38 Ref.

Descriptors: *Meanders, *Rivers, *Geomorphology, River flow, Symmetry, Asymmetry.

Evidence is presented to demonstrate that most meander loops are asymmetrical and, more important, that the nature of this asymmetry is not random, but well-defined and consistent. That preferred asymmetry should exist in meander loops does not appear to be the result of chance but seems to reflect certain inherent features of flow through bends. Two forms of asymmetry indicative of flow direction are often displayed. One is downchannel delay in the inflection point of meanders, producing traverses which are dominantly convex facing downvalley. The other is upvalley skew in the axis of gooseneck loops. An index of inflection asymmetry is presented and applied to 15 rivers; the data confirm the statistical preference for delayed inflection. An explanation of the phenomenon is offered based on the hydraulics of flow through bends. Of major importance appears to be the persistence downchannel of patterns of helical circulation and the cross-sectional distribution of longitudinal velocity well past the bend that forms them. The upvalley skew of goosenecks is, in many cases, nothing more than an extreme form of convex-downvalley looping, maintained as meanders have increased their tortuosity. Some goosenecks, however, show no delayed inflection and appear to develop from differences in rates of downvalley migration between adjacent meander traverses. It is concluded that the minimum variance theory and the sine-generated model of meanders should now be discarded. (Baker-FRC)

TIME OF TRAVEL OF THE FLINT RIVER, UTAH DAM TO HIGHWAY M-13, MICHIGAN: AUGUST 4-8, 1981,
Geological Survey, Lansing, MI. Water Resources Div.
T. R. Cummings, and J. B. Miller.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver CO 80225, Price: $3.50 in paper copy, $4.00 in microfiche. USGS Open-File Report 82-853, August 1982. 21 p, 12 Fig, 4 Tab.

Descriptors: *Dye releases, *Tracers, *Dispersion, Mixing, *Water pollution sources, *Waste assimilative capacity, Waste dilution, Waste disposal, Flint River, Genesse County, *Michigan.

The tracing of Rhodamine WT dye has provided time-of-travel data for waste-load allocation studies of a 42.8-mile reach of the Flint River at low flow. Dye was injected at two locations in Flint--at Utah Dam and at Grand Traverse Street. From Utah Dam to Grand Traverse Street the mean velocity of flow was 0.1 foot per second; time-of-travel was 35.3 hours. From Grand Traverse Street to Highway M-13, mean velocity was 0.7 foot per second; time-of-travel was 78.8 hours. Time-of-travel for the reach between Utah Dam and Highway M-13 was thus 114 hours. A discharge of equaled or exceeded about 90% of the time was measured at Grand Traverse Street in Flint before dye injection. (USGS)

MAGNITUDE AND FREQUENCY OF FLOODS IN EASTERN OREGON,
Geological Survey, Portland, OR. Water Resources Div.
D. D. Harris, and L. E. Hubbard.
USGS Water Resources Investigations Report 82-4078, 1983. 39 p, 7 Fig, 4 Tab, 39 Ref.

Descriptors: *Flood frequency, *Peak discharge, Natural flow, Flood forecasting, Analytical techniques, *Oregon, Log Pearson type III.

A method for estimating the magnitude and frequency of floods is presented for unregulated streams in eastern Oregon. Equations relating flood magnitude to basin characteristics were developed for exceedance probabilities of 0.5 to 0.01 (2- to 100-year recurrence intervals). Separate equations are presented for four regions: Southeast, Northeast, North Central, and Eastern Cascades. Also presented are values of flood discharges for selected exceedance probabilities and of basin characteristics for all gaging stations used in the analysis. Included are data for 148 stations in Oregon, 3 stations in northern California, 3 stations in western Idaho, 4 stations in northern Nevada, and 4 stations in southern Washington. Drainage areas used in the analysis range from 0.47 to 11,300 square miles. Also included are maximum discharges for all eastern Oregon stations used in the analysis. (USGS)

Nordic Hydrology, Vol 13, No 5, p 279-292, 1982. 5 Fig, 10 Ref.

Descriptors: *Aquifers, *Groundwater recharge, Percolation, Limestone, Greensand, Sand, Lithology, Quaternary deposits, Hydrology, Infiltration, Denmark, Susa catchment.

Archive data and borehole logging were used to study a pre-Quaternarygreensand limestone aquifer at Susa, Denmark. The aquifer was composed of layers of different lithology, i.e., clay marl, lime sand, limestone and hardgrounds, which dip slightly toward the northwest and are cut by faults. The fault zones, together with a fracture system in the top layers of the aquifer caused by ice pressure, localize zones of high hydraulic conductivity. The hydraulic negative boundaries are found in zones of low hydraulic conductivity mainly within the fault blocks. Both the hydraulic gradient and the hydraulic conductivity decrease with depth in the aquifer. The main part of the groundwater flow is thus taking place at the upper part of the aquifer. The hydrogeology of the Quaternary acquifers was studied by means of environmental tritium levels. Depth of penetration of the tritium was found and hydraulic properties such as actual velocity, hydraulic conductivity and leakage factors have been estimated. Point values of infiltration are given for the two localities at 100-150 mm/year. The groundwater recharge to the limestone aquifers underlying the Quaternary deposits are estimated at between 55-105 mm/year. The distribution of the two lithological types is important for determining areas with downward percolation and areas where a hydrological circuit in the upper layers reduces downward percolation. (Baker-FRC)

A DISTRIBUTED GROUNDWATER/SURFACE WATER MODEL FOR THE SUSA-CATCHMENT. PART II - SIMULATIONS OF STREAMFLOW DEPLETIONS DUE TO GROUNDWATER ABSTRACTION,
Technical Univ. of Denmark, Lyngby.
J. C. Refsgaard, and E. Hansen.
Nordic Hydrology, Vol 13, No 5, p 311-322, 1982. 5 Fig, 1 Tab, 2 Ref.

Descriptors: *Aquifer recharge, *Groundwater, *Model studies, Susa catchment, Catchment areas, Denmark, Groundwater abstraction, Confined acquifers, Streamflow.

The distributed groundwater/surface water model as presented has been successfully tested on historical streamflow data from the Koge A catchment, which is heavily influenced by a groundwater abstraction. The physical mechanisms of streamflow depletion due to groundwater abstraction in catchments where a confined acquifer is overlaid by Quaternary drift deposits have been discussed and illustrated by some simulation results. The large scale effects of a groundwater abstraction on the recharge and steamflow are illustrated. The relative streamflow depletion has been shown to vary considerably from one catchment to another and to depend heavily on the size of the groundwater abstraction. Consequently it is not possible to assign a general streamflow depletion curve, neither to the entire Susa area nor to the individual sub-catchments. For confined acquifers it was found that the location of pumping wells in practice has negligible influence on the streamflow depletion. (Baker-FRC)
W84-00377

A DISTRIBUTED GROUNDWATER/SURFACE WATER MODEL FOR THE SUSA-CATCHMENT, PART I - MODEL DESCRIPTION,
Technical Univ. of Denmark, Lyngby.
J. C. Refsgaard, and E. Hansen.
Nordic Hydrology, Vol 13, No 5, p 299-310, 1982. 8 Fig, 12 Ref.

Descriptors: *Model studies, *Groundwater recharge, Catchment areas, Susa-catchment, Denmark, Evapotranspiration, Streamflow, Hydrology, Aquifers.

A distributed hydrological model has been developed for the Susa catchment, covering about 1,000 sq km of Zealand, Denmark. The landscape is a moraine type formed by glaciers during the last glacial period. The pre-Quaternary aquifer consists of Paleocene deposits and Danian limestone. It is overlayered by glacial deposits, predominantly consisting of moraine clay, yet with some few areas with sandy soil. The model gives a physically based description of the main processes in the entire land phase of the hydrological cycle. The model simulates seasonal as well as year-to-year variations in the hydrological regime of the catchment as a consequence of changing hydro-meteorological and climatological conditions as well as of the influence of man. Almost all the model parameters are physical parameters such as transmissivities, storage coefficients, topographical data, field capacity, and leaf area index. The model has general applicability in areas with similar hydrogeological conditions. This would be the case for a low confined aquifer with relatively large transmissivities overlayered by low permeable saturated deposits and the phreatic surface rather close to terrain. Calibrations and test simulations have been presented for the Susa catchment with respect to hydraulic heads of the confined aquifer, stream flow and soil moisture. Seasonal and year-to-year variations in the hydrological regime have been considered. (Baker-FRC)

LONG-TERM VARIATIONS OF GROUNDWATER RESOURCES OF THE NORTHERN HEMISPHERE,
R. K. Klige, and V. S. Kovalevskii.
Water Resources (English Translation), Vol 9, No 3, p 263-271, May-June, 1982. 6 Fig, 1 Tab, 23 Ref. Translated from Vodnye Resursy, No 3, p 57-66, May-June, 1982.

Descriptors: *Groundwater management, *Water resources development, *Climatology, USSR, United States, Runoff, Rivers, Water supply, Water demand, Forecasting, Mathematical equations, Water levels.

The long-term trend of recharge of groundwater resources was studied using data from chronological runoff series occurring mainly during the winter low-water period at which time rivers are fed primarily by groundwaters. The data were collected from more than 1000 gauging stations over 15-80 years, with the bulk of the series having a duration of 25-40 years. As a result of the study a complex equation was ultimately derived for calculating variations of the groundwater level and the deviations from them of the mean long term value during 1929-1970, taking into account both climatic changes and the anthropogenic effect expressed in world water consumption. At present long-term variations of groundwater resources are related 80-90% to climatic factors. The equation permits reconstruction of the variation of the groundwater levels during the period for which there are data on the basis of the parameters figuring in it from 1893-1975 and even forecasting their variation within 12 years, 1976-1987, with consideration of the lag time. The noted general trends of the long-term variation of groundwater resources agree well with a number of other natural processes such as the retreat of glaciers and shoaling of closed lakes and the increase of the level of the World Ocean as well as the decrease of land water supplies and the analogous increase of water supplies in the ocean. It is concluded that, if the current climatic conditions stay the same, a further decrease of groundwater resources is possible. This process can be intensified considerably during warming of the climate under the effect of further anthropogenic influences on it. (Baker-FRC)

lands, Wetting, Infiltration, Groundwater
rge, Aquifers, Water table, Groundwater
d.

the infiltration wetting front from a river bed
ephemeral stream in flood reaches the shal-
vater table, the rate of recharge, which is also
f infiltration, is affected by the development
roundwater mound. The effect is practically
diate if the water content behind the wetting
is close to saturation. An approximate analyt-
olution is developed in that case, which pre-
the time dependence of the recharge rate.
arison with experimental results in th labora-
shows that the solution is excellent in spite of
ssumptions necessary in the derivations. As
as the ratio of river width over depth to water
exceeds 2 and as long as the ratio of initial
ated thickness over depth to the water table
ds 2.5, the analytical solution is essentially
. Under most field conditions these ratios are
y exceeded. Consequently, the predictive
ion for the time dependence of the recharge is
quite simple to use and adequately accurate
eld applications. (Author abstract)

Cavern flow.

mputer program was developed for the two-
nsional unsteady flow of water beneath a
r table toward parallel tunnel-shaped caverns
vated in saturated rock of low permeability for
urpose of storing oil or LPG. A numerical
ne, based on the boundary integral elements
od, was used to determine the water table
on, the inflow to the galleries, and the velocity
ne perimeter. Both oil-filled and air-filled cav-
were considered. While the shape of the gal-
s was constant, the spacing between them and
distance to an impervious bottom were varied.
erical results permitted calculation of the time
ired for the water table to drop from its initial
ion to the gallery top or to the product level,
water velocity on the gallery perimeter, and
otal inflow to the gallery. The dimensionless
city of descent of the water table above and
the top of the cavern was practically constant
insensitive to geometry. The dimensionless
required for the free surface to drop from the
rn top to the height near that of the oil level
also practically constant. The influence of the
zontal impervious boundary was negligible.

lic conductivity, *Coastal aquifers, Saline
er intrusion, Aquifer properties, Clays, Perme-
ity, Fate of pollutants.

nges in hydraulic conductivity of Israeli coast-
ediments (<5% clay) produced by flushing
h seawater followed by fresh water were stud-
in laboratory columns. Hydraulic conductiv-
ities decreased by a maximum of 0.1 to 0.001 of the original values whenever seawater was flushed from the soil by fresh groundwater. Subsequent flushing with seawater did not significantly restore the original hydraulic conductivities. Using synthetic waters with CaC12 and NaC1 at the same ionic strengths as the natural waters showed that the decrease in hydraulic conductivity was caused by an incipient stage of gel formation. The small water-clay bodies closed the spaces between pores. Results show that a shift of the seawater-fresh water interface in an aquifer containing even a small percentage of clays can create a relatively permanent, almost impermeable boundary in the region of the interface. Attempts to change this interface position by injecting fresh water would likely produce an impermeable boundary within a short time. (Cassar-FRC)

**REPORT ON GROUND WATER DEPEND-
ENCE IN NEW YORK STATE.**
New York State Dept. of Health, Albany. Bureau of Public Water Supply Protection.
1981. 47 p, 2 Fig, 3 Tab, 1 Append.

Descriptors: *Groundwater availability, *Groundwater depletion, *Groundwater storage, *Aquifers, *Aquifer systems, Available water, Groundwater basins, Aquifer management, Water supply, Water use, Water users, Aqueducts, *New York.

Recently, attention has focused on averting the possible degredation of New York State's groundwater resources. Toward this end, it must be determined which areas use groundwater as a significant source of portable water, and where the major aquifers are located. This report describes the groudwater use of three geographic areas of New York State: Long Island, New York City and upstate New York. On Long Island, the population of the counties of Nassau and Suffolk are 99.88% dependent on groundwater, while New York depends for the most part on surface water for its supply. The New York City aqueduct system supplies 93% of the population. In upstate New York, the availability of groundwater as a source of drinking water varies widely from area to area. Approximately 36% of the upstate population of 7,880,000 uses groundwater as their source of drinking water. The eighteen primary aquifers in New York State are in unconsolidated sand and gravel deposits. To determine their locations, source and treatment, files were searched for groundwater supplies serving populations of 8,000-10,000 or for supplies serving smaller populations of 5,000-6,000 with both surface and groundwater usage. These records were then used in conjunction with USGS reports and county water supply maps. (Garrison-Omniplan)

**PRELIMINARY APPRAISAL OF THE HY-
DROLOGY OF THE BLOCKER AREA, PITTS-
BURG COUNTY, OKLAHOMA,**
Geological Survey, Oklahoma City, OK. Water Resources Div.
M. V. Marcher, D. L. Bergman, J. D. Stoner, and S. P. Blumer.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver CO 80225, Price: $12.00 in paper copy, $5.00 in microfiche. USGS Open-File Report 81-1187 (WRI), 1981. 48 p, 9 Fig, 14 Tab, 13 Ref.

Descriptors: *Hydrologic data, *Groundwater, *Surface water, *Water quality, Groundwater movement, Groundwater recharge, Wells, Water level, Streams, Rocks, Strip mining, Chemical analysis, *Oklahoma, Pittsburg County, Blocker.

Bedrock in the Blocker area of southeastern Oklahoma consists principally of shale, siltstone, and sandstone of the Boggy and Savanna Formations of Pennsylvanian age. These rocks have been folded to form the Panther Mountain syncline on the south and the Kinta anticline on the north. Alluvium along streams is less than 15 feet thick and consists mainly of sandy silt. Water in bedrock is under artesian conditions. Well depths range from 11 to 213 feet and average 75 feet. In 86% of the wells measured, the water level was less than 30 feet below the land surface. Because the rocks have minimal permeability, well yields probably are less than 5 gallons per minute. Ground water is commonly a mixed cation bicarbonate type with dissolved solids ranging from about 300 to 2,000 milligrams per liter. No relationship between water chemistry and well depth or geographic distribution is apparent. Streams in the area are ephemeral and there are extended periods of no flow. Blue Creek was dry 30% of the time during 1976-80 and had flows of less than 0.1 cubic foot per second for at least 80 consecutive days. Stream water is generally a mixed cation sulfate type. The maximum dissolved-solids concentration determined in stream water was 3670 milligrams per liter. Maximum suspended sediment discharge, in tons per day, was about 235 for Blue Creek, 40 for Blue Creek tributary, and 630 for Mathuldy Creek. Silt-clay particles (diameters less than 0.062 millimeter) are the dominant sediment size. Surface mining for coal undoubtedly will have some effect on the environment. The most likely deleterious effects are increased sediment loads in streams and increased mineralization of stream waters. However, these effects should be of only limited extent and duration if appropriate mining and reclamation practices are followed. (USGS)

**EFFECTS OF UNDERGROUND MINING AND
MINE COLLAPSE ON THE HYDROLOGY OF
SELECTED BASINS IN WEST VIRGINIA,**
West Virginia Geological and Economic Survey, Morgantown.
W. A. Hobba, Jr.
West Virginia Geologic and Economic Survey Report of Investigation RI-33, 1981. 77 p, 57 Fig, 3 Tab, 24 Ref.

Descriptors: *Base flow, *Subsidence, *Mine drainage, *Surface-groundwater relations, Geologic fractures, Permeability, Water table, Observation wells, Runoff, Hydrologic budget, *West Virginia.

The effects of underground mining and mine collapse on the hydrology of an area where the mined bed of coal lies above major streams, and in another area where the bed of coal lies below major streams, are described. Subsidence cracks at land surface generally parallel predominant joint sets in the rocks. The mining and subsidence cracks cause increased infiltration of precipitation and surface water, decreased evapotranspiration, and higher base flows in some small streams. Groundwater levels in observation wells in under-mined areas fluctuate as much as 100 feet annually. Both gaining and loosing streams are found in under-mined areas. Mine pumpage and drainage generally cause diversion of water underground from one basin to another. Areal and single-well aquifer tests indicated near-surface rocks have higher transmissivity values in a mine-subsided basin than in unmined basins. Increased infiltration and circulation through near-surface rocks increases dissolved

mineral loads in streams, as do treated and untreated contributions from mine pumpage and drainage. Abandoned and flooded underground mines make good reservoirs because of their increased transmissivity and storage. Subsidence cracks were not successfully detected by thermal imagery, but springs and seeps were detected and mapped. (USGS)

HYDROLOGY OF THE FLORIDIAN AQUIFER IN NORTHWEST VOLUSIA COUNTY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
A. T. Rutledge.
USGS Water-Resources Investigations, Open-File Report 82-108, 1982, 165 p, 51 Fig, 1 Map, 10 Tab, 13 Ref.

Descriptors: *Aquifer, Recharge, Discharge, Irrigation, *Irrigation wells, *Drawdown, Sinkholes, Flow-net analysis, Water budget, Saltwater intrusion, Aquifer testing, *Florida, Northwest Volusia County, *Floridan aquifer.

The characteristics of the Floridan aquifer in northwest Volusia County and the effects of fernery irrigation withdrawals from the Floridan aquifer were studied. The large irrigational withdrawals, especially in winter months when spray irrigation is used for freeze protection, introduce problems such as the potential for saltwater intrusion, the temporary loss of water in domestic wells caused by large potentiometric drawdown, and increased sinkhole activity. Average ground-water irrigational withdrawal is 8.1 million gallons per day while peak withdrawal rate is 300 million gallons per day during freeze-protection pumpage. Transmissivities of the Floridan aquifer range from 4,500 to 163,000 feet squared per day. Highest transmissivities are in the DeLeon Springs area and the lowest are in the east Pierson area. The drawdown in the Pierson area at the end of one intense pumpage exceeded 30 feet over a 4.4 square mile area. A significant amount of the withdrawn water was replaced by leakage during the pumping period. No long-term residual drawdown has occurred. Sinkhole activity has been increased by the temporary increase in load on the aquifer's skeletal structure during intense potentiometric drawdowns. There is no evidence of saltwater intrusion, but a monitoring network for future early detection is suggested. (USGS)

The Hood Basin in north-central Oregon co
of about a 1,035-square-mile area underlai
Miocene to Holocene age volcanic, volcanic
sedimentary rocks, and unconsolidated surfici
posits. The most important aquifer is the Col
River Basalt Group, a unit that underlies m
the basin and probably exceeds a thickness of
feet wherever it is present. By 1980, only the
1,000 feet or less of the formation has been d
oped for water supplies. Most of this develop
is in the semiarid eastern half of the basin. We
the aquifer unit generally yield from 15 to
gallons per minute and a few yield as mu
3,300 gallons per minute. Other aquifer units i
basin have more limited areal extent and sm
saturated thickness than does the Columbia
Basalt Group. Generally, these units are capal
yielding from a few to a few hundred gallon
minute to wells. Most of the ground water i
basin is chemically suitable for domestic, irriga
or other uses. Some ground water has objec
able concentrations of iron (0.3 to 6.4 mg/l)
manganese (0.05 to 1.2 mg/l) or is moderately
to very hard (60 to 260 mg/l) as calcium ca
ate. (USGS)

GROUND-WATER DATA FOR GEORGIA,
Geological Survey, Doraville, GA. Water
sources Div.
S. E. Matthews, W. G. Hester, and M. P. O'By
USGS Open-File Report 81-1068, 1981. 94 p
Fig, 24 Ref.

Descriptors: *Groundwater, *Water le
Aquifers, *Georgia, Water quality, *Groundw
levels, Groundwater quality.

More than 2,000 water-level measurements m
in Georgia in 1980 provided the basic data for
report. Daily mean water-level fluctuations
trends are shown in hydrographs for the prev
year and fluctuations of the monthly mean w
level are shown for the previous 10 years in sel
ed observation wells in Georgia. Monito
ground-water levels is essential to the understa
ing of storage changes in a ground-water reser
or aquifer. Fluctuations and long-term trend
water levels occur as a result of recharge to
discharge from the reservoir. Mean annual w
levels across Georgia were from 1.92 feet highe
12.61 feet lower in 1980 than in 1979, and in so
areas were the lowest on record. (USGS)

tors: *Groundwater recharge, Geohydro-
eologic fractures, Cavitation, Permeability,
n basins, *Aquifers, Paleozoic aquifers,
severing, *Wyoming, Foreland basin, Lara-
rust faults.

echarge areas for the major Paleozoic
in the Wyoming foreland basins fall into
road classes ranked from least to most effi-
hydraulic interconnection with the aquifers
asins: (1) fault severed, (2) continuous ho-
s, and (3) obliquely faulted. The fault sev-
d continuous homoclines classes each en-
s slightly less than half the basin perimeters
aking these types very common. Recharge
deep basins is precluded along the fault
boundaries. Consequently independent cir-
systems develop in the hanging wall
mountainward from the basin perimeter.
f the recharge water which enters the re-
areas along the homoclinal margins is re-
from the aquifer before entering the deep
the basin. This results because the diagene-
esses of recrystallization, cementation, and
tion have operated to reduce or destroy
bility basinward from the recharge areas
he recharge areas became differentiated
ne basin proper. In both the fault severed
moclinal margin cases, recharge along the
erimeters is precluded or diminished over
bilities determined for the aquifers from the
e areas. The consequences of this finding
ofold: (1) development of ground water
e Paleozoic rocks in the interior parts of the
ve Wyoming artesian basins is largely unfa-
, and (2) developers are forced to limit their
for the best prospects to the recharge zones
he perimeters of the basins. The immediate
: (1) the target drilling areas are dramatical-
ced to a small percentage of the basin
s, and (2) development in the recharge areas
es with existing surface water rights.

WATER RESOURCES OF THE BLACK HAND SANDSTONE MEMBER OF THE CUYAHOGA FORMATION AND ASSOCIATED AQUIFERS OF MISSISSIPPIAN AGE IN SOUTHEASTERN OHIO,
Geological Survey, Columbus, OH. Water Resources Div.
S. E. Norris, and G. C. Mayer.
USGS Open-File Report 82-170, 1982. 95 p, 18 Fig, 3 Tab, 17 Ref.

Descriptors: Hydrogeology, *Aquifer characteristics, Water resources, Groundwater movement, Specific capacity, Transmissivity, *Ohio, Coal hydrology, Black Hand Sandstone Member of the Cuyohoga Formation.

The Black Hand Sandstone Member of the Cuyahoga Formation and associated acquifers of Mississippian age, including the Allensville Conglomerate Member of the Logan Formation, (both members of the local usage) were investigated in a 1,500-square-mile area in southeastern Ohio. These aquifers are the chief sources of water beneath the coal-bearing rocks of the Pennsylvanian System and are widely use for farm and home requirements. The aquifers crop out in the western part of the area and dip southeastward 35 feet per mile. At Lake Hope, in northeastern Vinton County, the aquifers are the deepest sources of ground water in Ohio, occurring at depths locally exceeding 700 feet. At McArthur, in Vinton County, the aquifers yield about 300,000 gallons per day for municipal and industrial use, but withdrawal has been accompanied by declining ground-water levels during the past 10 years in a 10-square-mile area. WATER RESOURCES OF THE ZUNI TRIBAL LANDS, MCKINLEY AND CIBOLA COUNTIES, NEW MEXICO,
Geological Survey, Albuquerque, NM. Water Resources Div.
B. R. Orr.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver CO 80225, Price: $26.00 in paper copy, $4.00 in microfiche. USGS Open-File Report 82-1013, 1982. 173 p, 25 Fig, 5 Tab, 34 Ref.

Descriptors: *Groundwater resources, *New Mexico, *Aquifer characteristics, *Water wells, Water quality, Springs, Hydrogeology, *Zuni Indian Reservation, Zuni Mountains, McKinley County, Cibola County, Well and spring inventory.

The sandstones and limestones of the Glorieta-San Andres aquifer and sandstones within the Chinle Formation provide most of the municipal, stock, and domestic water supply to the Zuni Indian Tribe in west-central New Mexico. Both aquifers are recharged at outcrops in the Zuni Mountains, and their hydraulic conductivity is significantly enhanced by fractures in the sandstones and by fracture-solution openings in the carbonate rocks. The range of well yields, from 5 to 150 gallons per minute, is attributed to fracture frequency, continuity, and distribution controlled by regional uplift and folding. Water in the Glorieta-San Andres aquifer is enriched in calcium and sulfate, and dissolved-solids concentrations range from 389 to 994 milligrams per liter. Water in the sandstones of the Chinle Formation is enriched in sodium and bicarbonate, and dissolved-solids concentrations range from 215 to 1,980 milligrams per liter. The Bidahochi Formation, a loosely consolidated sand and gravel unit mantling western parts of the reservation, could provide an additional source of water chemically suitable for most uses. Preliminary seismic-reflection studies showed a buried drainage system eroded in Triassic bedrock underlying the Bidahochi. Filled channels may contain sufficient saturated material to supplement existing water supplies. (USGS)

GROUND-WATER APPRAISAL OF THE PINE BUSH AREA, ALBANY COUNTY, NEW YORK,
Geological Survey, Albany, NY. Water Resources Div.
D. S. Snavely.
USGS Water-Resources Investigations Report 82-4000, 1983. 64 p, 11 Fig, 8 Tab, 10 Ref.

Descriptors: *Aquifer characteristics, *Sand aquifers, *Groundwater availability, Water table, *New York, Pine Bush, Albany County, Glacial lake, Albany, Groundwater model, Road salt, Water quality.

The 32-square-mile central part of the Pine Bush was studied to determine the availability of ground water in the surficial sand and to assess the quality of the water, especially with respect to phosphorous, nitrogen, and chloride. The surficial sand is from 5 to 150 feet thick and has a hydraulic conductivity of 68 feet per day. Recharge is solely by precipitation. Depth to water is about 10 feet but ranges from 5 to 20 feet locally. The water table and total precipitation have been declining since 1979. A computer model was used to simulate drawdowns that would be produced by pumping the aquifer at various rates. Results indicate that a single well could yield from 150 to 600 gallons per minute, depending on hydraulic conductivity, which was simulated at 25, 50, and 100 feet per day, allowing a maximum drawdown of 80% of total saturated thickness. Ground water contained low phosphorous (maximum of 0.04 mg). (USGS)

ANALYSIS OF THREE TESTS OF THE UNCONFINED AQUIFER IN SOUTHERN NASSAU COUNTY, LONG ISLAND, NEW YORK,
Geological Survey, Syosset, NY. Water Resources Div.
J. B. Lindner, and T. E. Reilly.
USGS Water Resources Investigations Report 82-4021, 1983. 65 p, 10 Fig, 7 Tab, 12 Ref.

Descriptors: *Groundwater, Mathematical models, Analytical techniques, *Aquifer characteristics, *Aquifer testing, Unconfined aquifer, *New York, Long Island, Radial-flow model, Stallman curves, *Drawdown.

Drawdown and recovery data from three 2-day aquifer tests (OF) the unconfined (water-table) aquifer in southern Nassau County, N.Y., during the fall of 1979, were analyzed. Several simple analytical solutions, a typecurve-matching procedure, and a Galerkin finite-element radial-flow model were used to determine hydraulic conductivity, ratio of horizontal to vertical hydraulic conductivity, and specific yield. Results of the curve-matching procedure covered a broad range of values that could be narrowed through consideration of data from other sources such as published reports, drillers' logs, or values determined by analytical solutions. Analysis by the radial-flow model was preferred because it allows for vertical variability in aquifer properties and solves the system for all observation points simultaneously, whereas the other techniques treat the aquifer as homogeneous and must treat each observation well separately. All methods produced fairly consistent results. The ranges of aquifer values at the three sites were: horizontal hydraulic conductivity, 140 to 380 feet per day; transmissivity 11,200 to 17,100 feet squared per day; ratio of horizontal to vertical hydraulic conductivity 2.4:1 to 7:1, and specific yield, 0.13 to 0.23. 2G. Water In Soils

WATER-REPELLENT SUBSTANCES AND AGGREGATE STABILITY IN HYDROPHOBIC SOIL,
G. Giovannini, S. Lucchesi, and S. Cervelli.
Soil Science, Vol 135, No 2, p 110-113, February, 1983. 4 Tab, 22 Ref.

Descriptors: *Water repellent soils, *Soil aggregates, *Soil erosion, Erosion, Chelation, Organic matter, Soil physical properties, Soil organic matter, Soil cement.

Solvent extraction of five naturally water repellent clay loam soils from Corleone, Sicily, reduced the water repellency of the samples. Water drop penetration times decreased from 484-540 sec to 124-155 sec with benzene extraction and 130-152 sec with benzene/acetylacetone. The extracts applied to 30 mesh and reduced the water stability index from 53-57 to 44-48 with benzene and to 33-38 with benzene/acetylacetone. Iron and aluminum complexed with organic matter were removed by benzene/acetylacetone, but not by benzene alone. Although aggregation reduces soil erodibility in most soils, in water repellent soils the hydrophobic coating restricts infiltration and causes intensive surface runoff and increased erosion. STOCHASTIC ANALYSIS OF ONE-DIMENSIONAL STEADY STATE UNSATURATED FLOW: A COMPARISON OF MONTE CARLO AND PERTURBATION METHODS,
Royal Inst. of Tech., Stockholm (Sweden). Dept. of Water Resources Engineering.
J. Andersson, and A. M. Shapiro.
Water Resources Research, Vol 19, No 1, p 121-133, February, 1983. 18 Fig, 1 Tab, 14 Ref.

Descriptors: *Unsaturated flow, *Soil water, *Infiltration, Stochastic hydrology, Subsurface flow, Hydraulic conductivity, Monte Carlo method, Drainage, Model studies, Spatial variation, Perturbation techniques.

The stochastic nature of moisture content in a soil profile under steady state, unsaturated infiltration is examined, where the saturated hydraulic conductivity is taken as a stationary stochastic process. Two different techniques are employed in determining the stochastic output. These are Monte Carlo simulations and an analytic derivation from a first-order perturbation solution. In comparing the two techniques, the liability of the perturbation expressions is investigated if the Monte Carlo results are assumed to exactly represent the stochastic nature of the moisture content. In four test examples a relatively good comparison is obtained between the results of the two techniques. The analytic nature of the perturbation solution then readily provides information concerning the general stochastic properties of the moisture content, and this way, additional Monte Carlo runs are avoided. From this analysis it is shown that the moisture content is a stationary stochastic process at distances far from boundary regions. The distance from the boundary to regions of stationarity is dependent upon soil properties and the boundary conditions imposed. (Author's abstract)

THE CROSS-COUPLING TRANSPORT COEFFICIENT FOR THE STEADY FLOW OF HEAT IN SOIL UNDER A GRADIENT OF WATER CONTENT,
California Univ., Riverside. Dept. of Soil and Environmental Sciences.
S. Y. Chu, G. Sposito, and W. A. Jury.
Soil Science Society of America Journal, Vol 47, No 1, p 21-25, 1983. 13 Ref.

Descriptors: *Heat flow, *Soil physics, *Thermodynamics, Soil water, Jury-Miller equation.

A theoretical discussion based on the thermodynamics of irreversible processes (TIP) is given concerning the flux equations for the coupled, steady flows of water and heat in a soil as formulated by Jury and Miller (1974). It is shown that a unique definition of the heat flux vector in a coupled flow process is not possible within the context of TIP alone, although differences between heat flux vectors can be defined uniquely. It is shown also that any set of coupled expressions for simultaneous, steady water and heat flow in soil that is compatible with TIP can be used to derive the Jury-Miller formulation of the flux equations by means of linear transformations. Moreover, the cross-coupling coefficient that links the heat flux to the gradient of water content vanishes identically in this formulation. However, a particular definition of the heat flux is implied by the Jury-Miller equations, and its relationship to the measured heat flux cannot be established solely by the methods of TIP. An examination of the data on heat and water flow reported by Jury and Miller indicated that the experimental sensitivity was not sufficient to discriminate among several alternative definitions of the heat flux that can be developed within TIP. This result serves to emphasize the point that the identification of the heat flux actually measured in a coupled flow experiment must be on the basis of either a theoretical model of the coupled flow processes or an application of the general equation of total energy balance. (Author's abstract)

2H. Lakes

MODEL OF LIGHT PENETRATION IN A TURBID LAKE,
Minnesota Univ., Minneapolis. St. Anthony Falls Hydraulic Lab.
H. G. Stefan, and J. J. Cardoni.
Water Resources Research, Vol 19, No 1, p 109-120, February, 1983. 21 Fig, 4 Tab, 30 Ref.

Descriptors: *Suspended solids, *Light penetration, Photosynthesis, Oxbow lakes, Turbidity, Lake Chicot, Arkansas, Lakes, Model studies, Radiation, Organic matter.

The attenuation of light with depth of water and the effect of suspended solids (clay, phytoplankton, and organic detritus) on the attenuation were described by equations for Lake Chicot, a 20 sq km highly turbid oxbow lake in Arkansas. Chlorophyll a affected total attentuation coefficients only at high concentrations; inorganic suspended solids dominated light attenuation in this lake. Since ligh attenuation is a function of wavelength, thre bands were distinguished: photosynthetically active radiation, visible light, and total radiation Light as seen by flat plate sensors and spherically integrated light as experienced by an algal ce were distinguished. A relationship was develope between incident total radiation measured abov the water to underwater photosynthetically activ radiation. (Cassar-FRC)

NUMBER, BIOMASS, AND PRODUCTION O BACTERIOPLANKTON OF THE KUIBYSHE RESERVOIR IN 1979,
Akademiya Nauk SSSR, Borok. Inst. Biolog Vnutrennykh Vod.
A. V. Ivatin.
Water Resources (English Translation), Vol 8, N 6, p 665-670, November-December, 1981. 2 Fig, Tab, 9 Ref. Translated from Vodnye Resursy, N 6, p 159-164, November-December, 1981.

Descriptors: *Reservoirs, *Bacteria, *Populatio dynamics, Bacterioplankton, Kuibyshev reservoi Seasonal variation, *USSR.

In 1979 studies were made on the Kuibyshev rese voir to trace the changes in the number and bio mass of bacterioplankton in time and space, t compare the time of doubling of the number an biomass of bacteria, and to determine the produc tion of bacterioplankton. The number of bacteric plankton in various stretches of the reservoi during the growing season varied from 0.39 to 4.3 million cells/ml and was highest at the time of th spring flood in May. A decrease of the number o microorganisms with a simultaneous decrease o water turbidity was observed from the uppe reaches of the reservoir toward the dam. Signifi cant differences in the number of bacterioplankto were not found in the surface and bottom wate layers. The distribution of the bacterioplankto between the surface and bottom layers and it change over the longitudinal profile of the reser voir in general features is similar to the corre sponding changes in the number of bacterioplank ton. The most intense multiplication and produc tion of biomass occurred in summer, indicating high activity of the microflora of the reservoi (Baker-FRC)

tion, *Rill erosion, Rills, Rainfall impact, Infil-
on.

odel of soil erosion, known as KYERMO, is
ented which emphasizes those processes which
important on steep slopes. Particular emphasis
aced on modeling rill development and geome-
since this is the least understood process in
ion mechanics. The model requires an input rill
ern. Rainfall inputs to the model require the
of breakpoint rainfall and kinetic energy. Sur-
storage is calculated on random roughness
of Linden (1979). Infiltration is modeled by
of the two layer Green-Ampt-Mein-Larson
el as proposed by Moore and Eigel (1981).
off is related to rainfall excess and surface
ge by the exponential relationships of Tholin
Kiefer (1960). Erosion is modeled separately as
and interrill erosion. Interrill erosion is mod-
by evaluating raindrop splash and interrill
sport capacity. Raindrop splash is predicted by
g the Bubenzer and Jones (1971) equation
ch requires kinetic energy, rainfall intensity,
percent clay. Interrill transport capacity is
eled by either the Yalin (1963) or Yang (1973)
tion depending on user preference. The rate of
very of soil to a rill is a minimum of either the
sport rate or splash rate. Rill detachment ca-
ty is calculated using the shear excess equation
oster (1982). Transport capacity is calculated
either the Yalin (1963) or Yang (1973) de-
ding on user preference. The distribution of
chment around the rill boundry is calculated as
nction of the shear distribution. Shear is distrib-
by using a modification of the area method of
dgren and Johnson (1964).

**RLD-WIDE DELIVERY OF RIVER SEDI-
NT TO THE OCEANS,**
ods Hole Oceanographic Institution, MA.
. Milliman, and R. H. Meade.
nal of Geology, Vol 91, No 1, p 1-21, 1983. 4
4 Tab, 68 Ref.

criptors: Rivers, *Oceans, *Sediment transport,
ment load.

mates based on both new and old data indicate
rivers with large sediment loads contribute about 7 x 10 to the 9th power tons of suspended sediment to the ocean each year. The data on which these estimates are based have a number of serious potential errors which need to be considered in either local or world-wide budgets. The most important factor is the widely variable quality of the data as a result of differences in measurement techniques, lengths of observation, and sampling procedures. The sediment loads of the large rivers in North America have been measured for as many as 50 years. Rivers draining the eastern part of the continent have small sediment loads. Rivers discharging into the Gulf of Mexico transport the greatest amount of sediment in the conterminous US. Sediment loads in rivers in the western part of the US are generally considered to be large, but again dams and reservoirs have decreased them considerably. Alaskan rivers that drain glaciers have much greater sediment yields. The largest river, the Amazon, still has a sediment load which is relatively unknown. The rivers that drain Europe are small and carry little sediment. Only the Rhone, Po, and Danube Rivers appear to have annual sediment discharges in excess of 10 x 10 to the 6th power tons. The Eurasian Arctic is drained by three large rivers, the Ob, Yenisei and Lena, all having drainage areas of about 2,500,000 sq km and water discharges of 385 to 560 cubic km/yr. However, the areas have been largely stripped of sediment by Pleistocene glaciers. River drainage in China and in the Asian continent exclusive of China are also considered. About 70% of the total river sediment delivered to the oceans is derived from southern Asia and the larger islands in the Pacific and Indian Oceans. (Baker-FRC)

PETROLOGY, CHEMISTRY, AND TEXTURE OF MODERN RIVER SANDS, AMAZON RIVER SYSTEM,
Amazonas Univ., Manaus (Brazil).
E. Franzinelli, and P. E. Potter.
Journal of Geology, Vol 91, No 1, p 23-39, 1983. 8 Fig, 6 Tab, 41 Ref.

Descriptors: *Sedimentation, *Sediment transport, Rivers, *Sand, Minerals, Quartz, *Amazon River, Subarctic regions, Temperate zones, Brazil, Peru, Ecuador, Colombia.

The thin section petrology and texture of the light minerals of 95 modern sands collected from the Amazon river system in Brazil and adjacent parts of Columbia, Ecuador, and Peru were examined. The sands derived from the Andes are lithic arenites, whereas sands derived from Precambrian terrains are much richer in quartz. Sands in rivers draining Tertiary molasse are also rich in quartz. Sand becomes more mature downstream along the main stem of the Amazon-Soliomes-Maranon, so that a sample analyzed at the mouth does not accurately reflect composition of the headwater. Enhanced maturity downstream results from dilution by quartz-rich tributaries and quartz-rich Tertiary outcrops, possible differential elimination of rock fragments, and even possible weathering on the modern flood plain of the Amazon. It is suggested that large subarctic and temperate rivers do not have a marked downstream increase in mineralogic maturity. River sands of Precambrian watersheds are coarser than those derived directly from either the Andes or from those derived from Tertiary molasse for two apparent reasons. First, Precambrian granites have coarser quartz than the reworked quartz of a major geosyncline, and second, tropical weathering eliminates quartzofeldspathic rock fragments much more rapidly than quartz. (Baker-FRC)

2K. Chemical Processes

IRON MINERALIZATION OF PERITIDAL CARBONATE SEDIMENTS BY CONTINENTAL GROUNDWATERS, FISHERMAN BAY, SOUTH AUSTRALIA,
Baas Becking Geobiological Lab., Canberra (Australia).
J. Ferguson, R. V. Burne, and L. A. Chambers.
Sedimentary Geology, Vol 34, No 1, p 41-57, 1983. 6 Fig, 3 Tab, 24 Ref.

Descriptors: *Iron, *Geochemistry, *Aquifer properties, Manganese, Fisherman Bay, Australia, Chemical precipitation, Sediments, Groundwater, Saline water, Geology, Bays.

Iron and manganese are precipitating from saline groundwaters flowing towards the hypersaline waters of Fisherman Bay, South Australia, from red bed aquifer systems in the coastal plain. In one area a lens-shaped body 500 sq m in area and 20 cm thick has formed. This contains ferric oxide at concentrations of 30%-70% by weight. Saline groundwaters associated with the iron mineralization contain up to 67.3 ppm Fe with pH of about 6. These high Fe concentrations are probably caused by: (1) adequate and readily soluble Fe in the aquifer, (2) biological activity which lowers the electrical conductivity without limiting Fe solubility by production of hydroxide or sulfide ions, and (3) absence of buffering minerals. Fe and Mn are separated in the bay sediments because Fe separates first, followed by Mn on the seaward fringe, where carbonates are found. The groundwaters in the aquifer system are potential ore-forming fluids. The present bay deposit has formed within 2000 to 6000 years. (Cassar-FRC)
W84-00418

THE COMPOSITION AND DEPOSITION OF ORGANIC CARBON IN PRECIPITATION,
New York State Coll. of Agriculture and Life Sciences, Ithaca.
G. E. Likens, E. S. Edgerton, and J. N. Galloway.
Tellus, Vol 35B, No 1, p 16-24, 1983. 1 Fig, 3 Tab, 34 Ref.

Descriptors: *Precipitation, *Organic carbon, Deposition, Acid rain, Particulate matter, Organic acids, Hubbard Brook, New Hampshire, Ithaca, New York, Forest watersheds, Chemical composition, Fate of pollutants, Water pollution sources.

Wet-only precipitation collected at Hubbard Brook (HB), New Hampshire, a heavily forested site, and Ithaca, New York, from June 1976 to May 1977 was analyzed for several types of organic carbon. Annual volume weighted mean concentrations (mg per liter) were: total organic carbon, 2.37 at Ithaca and 1.28 at HB; dissolved organic carbon, 1.88 at Ithaca and 1.09 at HB; and particulate organic carbon, 0.49 at Ithaca and 0.20 at Hubbard Brook. Deposition of total organic carbon was 24,230 g per ha at Ithaca and 14,031 g per ha at HB. Organic material concentrations and rainfall levels were highest in June-September. Particulate plus dissolved macromolecular (>1000 MW) organic matter accounted for 51% and 63% of total organic carbon at HB and Ithaca, respectively. The remainder of the carbon, the fraction containing compounds of <1000 MW, consisted largely of carboxylic acids, aldehydes, carbohydrates, tannin/lignin, primary amines, and phenols. Sources of the organic materials were airborne soil dust and plant material. The organic acids present in the rain at HB contributed only 2% of the total acidity. (Cassar-FRC)

ACID PRECIPITATION IN SOUTHEASTERN WYOMING,
Wyoming Univ., Laramie. Water Resources Research Inst.
J. Ahern, and C. Baird.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-132521, Price codes: A06 in paper copy, A01 in microfiche. Completion Report, September 1983. 96 p, 3 Fig, 17 Tab, 33 Ref, 6 Append. OWRT A-032-WYO(1), 14-34-0001-1154.

Descriptors: *Acid rain, Snow, Snowpack, Chemical properties, Hydrogen ion concentration, Chemical analysis, Laramie, *Wyoming, Snowy range.

Snowfall, snowpack, and rainfall samples were collected in Laramie, Wyoming and in the Snowy Range west of Laramie from March to June 1981 to determine the occurrence and sources of acid precipitation in southeast Wyoming. Electrodes measured different pH values in the samples; how-

ever, fast-response electrodes yielded higher and apparently more accurate pH measurements. The pH values in the Laramie precipitation and snowpack were typically greater than 5.0, but all the Snowy Range snowpack pH values were less than 5.0. The lower pH values in the Snowy Range snowpack were caused by higher concentrations of the acid-forming nitrate and lower concentrations of the neutralizing calcium. Two organic species, formate and acetate, were detected in the Laramie samples, but had no significant influence on the acidity of the samples.

3. WATER SUPPLY AUGMENTATION AND CONSERVATION

3A. Saline Water Conversion

DESALTING--A WATER SUPPLY ALTERNATIVE FOR VIRGINIA BEACH,
Pirnie (Malcolm), Inc., Newport News, VA.
M. P. Robinson, Jr., G. P. Westerhoff, and T. M. Leahy, III.
Journal of the American Water Works Association, Vol 75, No 3, p 109-117, March, 1983. 8 Fig, 5 Tab, 15 Ref.

Descriptors: *Water supply, *Brackish water, *Wastewater renovation, Desalination, Water treatment, Virginia Beach, Virginia, Membrane processes, Costs, Reverse osmosis, Water demand, Social aspects, Seawater, Demineralization, Energy, Regulations.

Desalting of brackish groundwater was chosen as a short-term practical alternative in a cost evaluation of 24 water supply options for Virginia Beach, Virginia. The city currently receives its water from Norfolk, which may not be able to satisfy water demands by the year 2000. The alternatives were grouped into 7 general headings: expanding regional surface water impoundments, expanding the Norfolk system, developing impoundments already existing, developing shallow groundwater aquifers, developing regional groundwater supplies, reclaiming wastewater, and desalting brackish groundwater or seawater. Costs per 1000 gal for several treatment techniques were: brackish water, $1.80-2.00; wastewater reclamation, $3.10-4.60; and seawater, $4.30-6.00. Improvements in reverse osmosis and other membrane processes are expected to reduce present costs by as much as 50%. However, energy costs are a highly significant part of cost evaluation. Wastewater reclamation and seawater desalting have the greatest promise for a long-term solution to Virginia Beach's water supply problems. (Cassar-FRC)

WIPED-FILM ROTATING-DISK EVAPORATOR FOR WATER REUSE,
California Univ., Berkeley. Water Thermal and Chemical Technology Center.
B. W. Tleimat, and T. Vermeulen.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-120880, Price codes: A05 in paper copy, A01 in microfiche. Technical Report RU-S2/15, U.S. Dept. of the Interior/OWRT, Washington, D.C., November 1982. 62 p, 20 Fig, 4 Tab, 14 Ref, 3 Append. OWRT C-00165-R(No 0537)(1), 14-34-0001-0537.

Descriptors: *Rotating-disk evaporator, *Wiped film. Distillation, Heat transfer, Energy consumption, Heat-transfer coefficient prediction and measurement, Modular design, Water reuse.

Two different disk designs for the wiped-film rotating-disk evaporator were built in order to compare their heat-transfer performance. In one design, 1 mm thick brass disks were spun-formed on a spherical mold; in the other, 0.8 mm-thick brass disks were made flat and the outside flange was formed by spinning. The heat-transfer coefficient was not influenced by the disk shape, but was affected unfavorably by surface roughness. Its analytical prediction agreed well with experimental results, showing overall heat-transfer coefficients as high as 28 kW/m super 2C (8000 Btu/hr ft super 2F) and 23 kW/m super 2C (6500 Btu/hr ft super 2F) for copper and brass disks respectively. A conceptual design of a five-effect vapor-compression system to desalt 10 m super 3/day (2500 gallons/day) from seawater was made and costed. Based on data obtained, with an overall temperature difference of 1.5F across the heat-transfer surface, the energy consumption by the compressor (50% isentropic efficiency) was calculated to be 6.2 kWh/m super 3 (23.6 kWh/1000gal) of product.

DEVELOPMENT OF A LARGE SPIRAL MODULE FOR SEAWATER DESALINATION BY REVERSE OSMOSIS,
UOP, Inc., San Diego, CA. Fluid Systems Div.
G. E. Foreman, and J. E. Beckman.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-125111, Price codes: A05 in paper copy, A01 in microfiche. Completion Report, September 1983. 53 p, 6 Fig, 3 Tab, 3 Append. OWRT C-80344-S(No 8573)(1), 14-34-0001-8573.

Descriptors: *Desalination apparatus, *Reverse osmosis, *Membrane filters, Reverse osmosis modules.

Work under OWRT Contract No. 14-34-0001-8573 was directed toward the development and testing of 12-inch diameter seawater reverse osmosis modules. The major development was the pressure tube assembly which resulted in the selection of an epoxy/fiberglass (FRP) pressure tube having an initial burst pressure in excess of 7200 psi. Safety as well as functionality was of prime importance. Twelve inch diameter spiral-wound elements containing 700 ft super 2 of active membrane were fabricated and ultimately tested at the Government Test Facility located at Wrightsville Beach, North Carolina. The modules provided performed well mechanically during the testing period verifying the tube design developed during the Contract. The elements, although sound mechanically, did not produce the quantity and quality of water originally anticipated. Chlorine in the feedwater caused some failures. It is suspected also that the product water channel material utilized may have contributed to lower than expected permeate flow.

OPTIMAL SELECTION OF MAJOR EQUIPMENT IN DUAL PURPOSE PLANTS,
Italconsult, Rome (Italy).
E. Gabbrielli.
Desalination, Vol 36/1, Jan 1981, p 1-23, 5 Fig, 4 Tab, 15 Ref.

Descriptors: *Desalination, Desalination plants, Dual purpose plants, *Economic evaluation, Combustion turbines, *Multistage flash distillation, Optimization.

Simulation of different operational conditions with the aid of a computer program is one of the best ways of assisting decision-makers in the selection of the most economic mix of equipment for a dual purpose plant. An economic comparison is provided of plants consisting of MSF desalinators and combustion gas or back pressure steam turbines coupled to low capacity electric power generators. The comparison is performed on the basis of the data made available by the OPTDIS computer program and the results are given in terms of yearly cost of production as the sum of capital, manpower, maintenance, fuel and chemical costs.

Poly(4-vinylpyridine), *Cellulose acetate.

The preparation of a novel asymmetric membr
case from a poly (4-vinylpyridine) and cellul
acetate homogeneous mixture is discussed. T
two polymers were miscible in concentrated so
tions. Asymmetric membranes were cast from
sexted dope mixture containing: chlorofo
methanol, acetone and formamide. The as-cast
lution, when coagulated in water at ambient te
perature, yields a highly plasticized asymmet
matrix which, upon slow diffusion of the chlo
form into the water, solidifies into a glassy st
The membranes following this stage, do not
quire annealing and yield high fluxes and salt rej
tion when tested in reverse osmosis. The asymm
ric morphology was confirmed by scanning el
tron microscopy studies which revealed a de
skin resting upon a highly porous, open-cell
foam-like structure. This structure retains its o
ginal wet dimensions upon drying. Brief attem
to quaternize the matrix are also reported.

IE EFFECT OF PRESSURE ON THE BULK OLYMER MICROSTRUCTURE IN CELLU- OSE ACETATE REVERSE OSMOSIS MEM- ANES,
greb Univ. (Yugoslavia). Faculty of Pharmacy l Biochemistry.
Arneri.
salination, Vol 36/1, January 1981, p 99-104, 3 , 16 Ref.

scriptors: *Desalination, Desalination plants, embranes, *Reverse osmosis, Polymers, Micros- cture pressure, Differential scanning calori- try.

e pressure effect on the bulk polymer micros- cture was investigated using Differential Scan- g Calorimetry (DSC). The samples of both nse' CA-398-3 membranes and Kesting dry mmetric CA-398-3 membranes investigated. e pressure treatment is also a kind of an 'anneal- ' process that orders the polymer microstruc- e. The effect takes place both in the case of the ginally more ordered (from a DSC point of w) polymer microstructure of 'dense' CA mem- nes and the originally less ordered (almost com- tely amorphous) polymer microstructure of the asymmetric CA membranes investigated. DSC rves on the thermoanalytical diagrams of the ssure treated 'dense' CA membranes show inly a shift of the endothermic peak (melting ocessu) to higher temperatures, and DSC curves the pressure treated Kesting dry asymmetric mbrane samples show both a shift of the endoth- nic peak to higher temperatures and quite an argement of the area under the peak. Pressure ion orders (densifies) the bulk polymer micros- cture of both the skin and porous layer of an mmetric CA reverse osmosis membrane.

EXPERIMENTAL STUDY OF SPRAY ASH EVAPORATION,
ushu Univ., Fukuoka (Japan). Research Inst. of dustrial Science.
Miyatake, T. Tomimura, Y. Ide, and T. Fujii.
salination, Vol 36, No 2, February 1981, p 113- , 11 Figs, 1 Tab, 16 Refs.

scriptors: *Desalination, *Distillation, Jets, lash evaporation, Sprays.

Spray flash evaporation was studied occurring in a superheated water jet injected through a circular tube nozzle into a low-pressure vapor zone. The effects of superheat, flow rate and nozzle diameter on spray flashing were pursued at 66C jet inlet temperature. From the experimental results, an empirical equation suitable for predicting the variation of liquid temperature with residence time was deducted.
W84-00456

PERFORMANCE OF A POLYPHOSPHATE-BASED SCALE CONTROL ADDITIVE IN AN MSF PLANT OF KUWAIT,
Kuwait Water Resources Development Centre, Shamiya.
F. H. Butt, and A. H. Bou-Hassan.
Desalination, Vol 36, No 2, February 1981, p 129-136, 4 Figs, 1 Tab, 4 Refs.

Descriptors: *Desalination, Desalination plants, *Distillation, Multistage flash, Kuwait, Polyphosphate-based additive, *Scaling.

Test of a polyphosphate-based scale control additive, carried out for a period of 8 months during 1978, showed that it was only moderately effective as a scale inhibitor. The gained out-put ratio, which was close to the design value of 8.0 at the start-up, declined by 30% during the test period while the distillate output fell off by about 25% in the same period. Even though the brine heater steam temperature was progressively increased from 93.3C to 118.3C, a steady decline was observed in the heater inlet and outlet temperatures which decreased from 81.7 to 73.3C and 86.7 to 79.4C respectively. It took only 40 days of operation for the heater fouling factor to exceed the design value. The fouling factor registered a five to seven-fold increase in 8 months.
W84-00457

A COMPARISON OF THE RELATIVE ECONOMICS OF SEA WATER DESALINATION BY VAPOUR COMPRESSION AND REVERSE OSMOSIS FOR SMALL TO MEDIUM CAPACITY PLANTS,
Israel Desalination Engineering Ltd., Tel-Aviv.
R. Matz, and U. Fisher.
Desalination, Vol 36, No 2, February 1981, p 137-151, 4 Figs, 8 Tab, 11 Refs.

Descriptors: *Desalination, Desalination plants, Seawater, *Vapor compression, *Reverse osmosis.

Lowest energy consumption is not necessarily the determining criterion for lowest cost sea water desalination. It is shown that at present-day market prices for plants, electrical energy, and fuel oil, Vapour Compression plants with horizontal aluminium tubes - the 'Ambient Temperature' Vapour Compression (ATVC) system - compares economically with Sea Water Reverse Osmosis (SWRO) even at the lowest net energy consumption achieved by the latter process by the use of high efficiency energy recovery turbines. This economic parity is shown to apply for plants of up to 4000 m super 3/day (1 mgd), and is shown to be maintained for future foreseeable developments resulting in reduced energy consumptions and more efficient plants. More areas for potential improvements are available for ATVC, than for SWRO, which may result in more favorable economics for the former process in the future.
W84-00458

REVERSE OSMOSIS IN THE DESALINATION OF BRACKISH WATER AND SEA WATER,
Hager and Elsasser G.m.b.H., Stuttgart (Germany, F.R.).
H. Ludwig.
Desalination, Vol 36, No 2, February 1981, p 153-178, 20 Figs, 5 Tab, 20 Refs.

Descriptors: *Desalination, Desalination plants, *Reverse osmosis, Seawater, Brackish water, *Polyamide hollow fiber modules.

To make RO an economical process, plant and operating costs have been reduced by developing compact modules, led by polyamide hollow fiber modules which recover energy from the reject when desalinating highly saline brackish water and seawater. Such plants only start to pay their way at product rates of around 400 cu m /d plus. Energy costs for desalination systems with lower capacities can also be reduced considerably by operating the RO plants at conversion rates of more than 30%. To what extent the required higher conversion rates can be obtained for a particular application depends on concentration of scale-forming content matter (calcium sulphate, strontium sulphate, barium sulphate and calcium carbonate), salt content of the raw water, concentration of fouling substances such as iron, manganese, anorganic and organic matter, risk of biological growth due to algae, shells and bacteria. The scope and type of conditioning and pretreatment are based on these factors.

APPLICATION OF REVERSE OSMOSIS TO AUTOMOTIVE ELECTROCOAT PAINT WASTEWATER RECYCLING,
Ford Motor Co., Dearborn, MI. Engineering and Research Staff.
J. E. Anderson, W. S. Springer, and G. G. Strosberg.
Desalination, Vol 36, No 2, February 1981, p 179-188, 2 Figs, 4 Tab, 11 Refs.

Descriptors: *Desalination, Desalination plants, *Reverse osmosis, Wastewater treatment, *Automative electrocoat paint, Water reuse.

Field and bench-scale RO experiments on wastewater derived from automotive electrocoat paint operations are reported. Field experiments were performed continuously over a 6 month interval using a RO unit equipped with cellulose acetate membranes. An operating pressure of 3100 kPa (450 psi) and a temperature of 24-27C was maintained. These RO experiments were unusual for two reasons. First, certain solutes in the feedwater were allowed to permeate through the membrane along with water. This was done to permit solute recycling and reuse. Since these solutes (ethyl, butyl and hexyl glycol ethers) were present in a 3% total concentration in the feedstream, their permeation through the membrane eliminated a flux reduction mechanism. This would arise from the increased upstream osmotic pressure if these solutes were concentrated. The experiments were performed under conditions where colloidal lead was present. This caused limited membrane fouling which was controlled via weekly cleaning with dilute lactic acid. Some supporting bench-scale RO experiments were carried out to probe factors influencing this RO application.

SOLAR DISTILLATION: THE SOLAR-ASSISTED CASE.
Sydney Univ. (Australia). Dept. of Chemical Engineering.
J. P. Gerofi, and G. G. Fenton.
Desalination: Vol 36, No 2, February 1981, p 189-204, 11 Figs, 1 Tab, 10 Refs.

Descriptors: *Desalination, Desalination plants, *Distillation, *Solar stills.

The case is considered where a solar collector system, without storage, is linked to an otherwise stand-alone, fuel-driven desalination plant. The choices involved in selecting the type of solar collector and the design constrains on other components of the thermal source loop are outlined. A rationale is outlined for determining the most economic collector area for such a situation and the proportion of the plant's energy requirement that can be provided by solar energy is discussed. Results for a specific collector desalination plant system, which include the effect of solar collector cost and fuel oil price on the economics, are presented. The decisions and constraints involved in selecting an optimum solar-assisted desalination system for a particular application are outlined.

RAYLEIGH-JEFFREYS STABILITY OF THERMOHALINE STRATIFIED FLUIDS SUBJECT TO VERTICAL FLOWS,
Technion - Israel Inst. of Tech., Haifa. Energy Engineering Center.
M. Bouscher, D. Pnueli, and Y. Zvirin.
Desalination, Vol 36, No 3, March 1981, p 307-333, 1 Fig, 9 Ref.

Descriptors: *Desalination, *Hydrodynamics, Fluid mechanics, Rayleigh-Jeffreys stability, Thermohaline stratified fluids.

The stability of an infinite horizontal layer of fluid with a density stratification due to both temperature and solute gradients, subject to an initial vertical flow field, is studied for different sets of homogeneous boundary conditions. Sufficient conditions for the maintenance of the original stratification, i.e. for stability, are obtained as a relation between the thermal Rayleigh number, and the solute Rayleigh number. A relation is obtained as a sufficient condition for stability for all sets of boundary conditions, and shows that the ratio of the solute to the thermal Rayleigh numbers is less than the negative of the square of the ratio of the solute is the thermal Prandtl numbers. This condition may thus be applied to cases in which the physical boundary conditions are not well defined, e.g. to practical engineering use of solar ponds. In addition, in conjunction with a similar result for initial horizontal flow fields, the result gives a sufficient condition for stability of arbitrary initial flows under all combinations of boundary conditions.

REVERSE OSMOSIS WITH A CELLULOSE ACETATE MEMBRANE IN THE REVERSE ORIENTATION,
Leiden Rijksuniversiteit (Netherlands). Gorlaeus Labs.
J. A. M. Smit.
Desalination, Vol 36, No 3, March 1981, p 291-297, 1 Fig, 1 Tab, 9 Ref.

Descriptors: *Desalination, Desalination plants, Membranes, *Reverse osmosis, *Cellulose acetate membranes.

Salt rejection curves of Cellulose acetate membranes placed with the porous layer towards the influent side and the skin towards the effluent side show typical maxima. Analysis of these maxima yields information on the salt permeabilities of the porous layer and of the skin in a rather direct way.
W84-00463

CONCENTRATION OF CUPRIC AND NICKEL IONS BY COMPLEXATION-ULTRAFILTRATION, SYNERGIC EFFECT OF SUCCINIC ACID,
Centre National de la Recherche Scientifique, Nancy (France). Lab. de Chimie Physique Macromoleculaire.
Q. T. Nguyen, Y. Jyline, and J. Neel.
Desalination, Vol 36, No 3, March 1981, p 277-283, 4 Fig, 6 Ref.

Descriptors: *Desalination, Ultrafiltration, Copper, Nickel, Ions, Succinic acid.

In ultrafiltration, high rejection of small ion species can be achieved by complexing these species with a suitable macroligand. The concentration was studied of cupric and/or nickel ions by ultrafication, through the DDS GR8 membrane, using polyethylenimine as a basic macroligand. The rejections of the metallic ions increased with the pH and the concentration of the polymeric ligand as expected. The addition of succinic acid (a molecular acidic chelating) to the mixtures allowed an improvement of the retentions of these ions at all pHs studied. This indicates that positive synergic effect was obtained by the formation of a mixed complex base-metal-acid.
W84-00464

ADSORPTION OF WATER ON CELLULOSE ACETATE MEMBRANE,
Tohoku Univ., Sendai (Japan). Faculty of Engineering.
Y. Kurokawa.
Desalination, Vol 36, No 3, March 1981, p 285-290, 3 Fig, 2 Tab, 3 Ref.

Descriptors: *Desalination, Desalination plants, Membranes, *Reverse osmosis, *Cellulose acetate, Casting, Adsorption.

The effect was studied of variables of cellulose acetate membrane procedure on its reverse osmosis properties by adsorption of water vapor. The rate of adsorption of vapor was slower for the membrane prepared at casting condition of longer evaporation period. This variation corresponded to that of water permeability by reverse osmosis performance. It seems from the isotherm data that the overall porosity of membrane is determined during the evaporation step. This provides additional support for membrane properties depending on casting conditions.

EFFECTS OF ACCELERATION ON REVERSE OSMOSIS DESALINATION,
SRI International, Menlo Park, CA.
G. B. Andeen.
Desalination, Vol 36, No 3, March 1981, p 265-275, 5 Fig, 8 Ref.

Descriptors: *Desalination, Desalination plants, Membranes, Reverse osmosis, Hollow fine fibers, Acceleration.

Hollow-fine-fiber reverse osmosis elements were run in a continuous-flow centrifuge at accelerations up to 1000 G. Under acceleration, the elements produced more desalted water and passed less salt, showing a reduction of concentration polarization. Reduced data showed that the mass transfer coefficient of salt from the membrane surface to the bulk of the brine increased with acceleration to the 0.3 power. Acceleration also improved flow distribution by eliminating regions of high-density stagnant brine. Use of a centrifuge will allow utilization of higher transport membranes.

RECENT DEVELOPMENTS IN THIN-FILM COMPOSITE REVERSE OSMOSIS MEMBRANE SYSTEMS,
UOP, Inc., San Diego, CA.
R. L. Riley, P. A. Case, A. L. Lloyd, C. E. Milstead, and M. Tagami.
Desalination: Vol 36, No 3, March 1981, p 207-233, 17 Fig, 8 Tab, 20 Ref.

Descriptors: *Desalination, Desalination plants, Membranes, *Reverse osmosis, *Water reuse, Thin film composite membranes, Jeddah, Saudi Arabia.

Desalination of seawater by reverse osmosis requires a membrane which approaches theoretical semipermeability and is sufficiently thin to p transport of water at practical operating pr and recovery rates. This objective has achieved by the development of a family film composite membranes based on nitroge taining polymers supported on a fabric-rein porous supporting membrane. The memb packaged in the spiral-wound configuration, it high water permeability, low salt perme thermal stability, resistance to micro-orga wet-dry, and chemical stability. Membranes type are currently employed for the conver seawater to potable water in the world's firs RO plant in Jeddah, Saudi Arabia, trailer-m U.S. Army military units, off-shore drillin forms, marine applications, and handpo emergency units. RO systems, employing th composite membrane elements, are also in ation for the conversion of brackish to p water and a variety of water-reuse applicatio textile finishing, boiler water for electrical u soft drink manufacturing, agricultural wate reclamation of municipal waste water.

M. Beccari, A. C. Di Pinto, A. Rozzi, M. San and L. Spinosa.
Desalination, Vol 37, No 3, June 1981, p 257- Fig, 2 Tab, 10 Ref.

Descriptors: *Desalination, Desalination *Vapor compression, Distillation, Vertical bundle, Falling brine film, Heat transfer.

Pilot-scale tests were carried out in order to more about the vapor compression process at erately high temperature (around 100C). O basis of the results obtained, a demonstration (about 240 m super 3/d) was built in order t the actual validity of the process developed. a new type compressor the energy consum was satisfactorily low. By the use of a vertica bundle with falling brine film established by distributors, it was also possible to obtain overall heat transfer coefficients.

UTILIZATION OF WASTE OF HOT WATER FOR DISTILLATION,
Indian Inst. of Tech., New Delhi. Centre of Energy Studies.
M. S. Sodha, A. Kumar, and G. N. Tiwari.
Desalination, Vol 37, No 3, June 1981, p 325-342, 9 Fig, 2 Tab, 8 Ref.

Descriptors: *Desalination, Desalination plants, Distillation, *Solar stills, Wastewater utilization, *Heated water.

The yield of a solar still can be increased by introducing hot feed water available from power and chemical plants; even in the absence of sun appreciable yields are obtained. The performance of a solar still was studied in two modes of wastewater utilization: (1) Flowing waste hot water from thermal power plants of constant rate through the solar still, (2) Feeding waste hot water obtained from thermal power plants once a day. Dependence of the distillate output on various operating parameters was investigated.

ENGINEERING MANAGEMENT OF DESALINATION PLANTS IN SAUDI ARABIA USING FUZZY DECISION ANALYSIS,
Riyadh Univ. (Saudi Arabia). Coll. of Engineering.
A. F. Abdul-Fattah.
Desalination, Vol 37, No 3, June 1981, p 343-350, 4 Fig, 1 Tab, 3 Ref.

Descriptors: *Desalination, Desalination plants, Management planning, *Saudi Arabia, Fuzzy set theory.

The fuzzy set theory is used in this analysis to help the decision-makers in selecting the most likely to succeed engineering management strategy for the operation of large desalination plants in Saudi Arabia. Five alternative strategies are suggested for the problem of desalination plants management. Fuzzy set theory and MAFDA computer code are used in the analysis. Fourteen criteria were selected. The final results show that the best solution is to use the computer and simulation strategy, and the second best is to use the local workers who had been trained in foreign countries.

EFFECT OF LIQUID TEMPERATURE ON SPRAY FLASH EVAPORATION,
Kyushu Univ., Fukuoka (Japan). Research Inst. of Industrial Science.
O. Miyatake, T. Tomimura, Y. Ide, M. Yuda, and T. Fujii.
Desalination, Vol 37, No 3, June 1981, p 351-366, 11 Fig, 1 Tab, 5 Ref.

Descriptors: *Desalination, Desalination plants, Spray evaporation, Temperature, *Evaporation, *Distillation.

To complement a previous experimental study of spray flash evaporation pursued at 60C jet inlet temperature, the effect was studied of liquid temperature on the spray flash evaporation by changing jet inlet temperatures to 40 and 80C. From the experimental results, a more general empirical equation suitable for predicting the variation of liquid temperature in the center of jet with residence time was deducted, and the recommendable operating conditions were proposed. Furthermore, an expedient method for prediction of the liquid temperature drop along the length of jet was devised for the recommendable operating conditions. Even at lower liquid temperatures, the spray flash evaporation still has higher evaporation performance and extremely faster evaporation rate than the flash evaporation occurring in other systems.

TEST AND EVALUATION OF 75,000 GALLON PER DAY CRYSTALEX PILOT PLANT.
Avco Systems Div., Wilmington, MA.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-128602, Price codes: A04 in paper copy A01 in microfiche. Completion Report, March 1977. 55p 17 Fig. 4 Tab. 5 Ref. -3255(1) 14-30-3255.

Descriptors: *Desalination plants, *Pilot plants, *Mechanical engineering, *Performance evaluation, *Design criteria, Desalination apparatus, Desalination, Hydraulic engineering, Freezing, Refrigeration, Water treatment, Process control, Evaluation, Flow rates, Design standards, Design flow.

A constructed 75,000 gallon/day (gpd) secondary refrigerant freezing (SRF) plant was moved to the Office of Water Research and Technology's Test Station on the North Carolina coast for testing. The plant was constructed to demonstrate an SRF process which used a non-flammable secondary refrigerant (R-114, dichlorotetrafluoroethane) and incorporated features which would permit construction of transportable packaged plants in capacities up to 100,000 gpd. The plant differed from early comparable size SRF plants in that it used: a smaller pressurized counterwasher than gravity-drained washers, and many elements sized for flows for 125,000 gpd if the wash column and freezer performed appropriately. The overall process of the direct-contact SRF desalting plant is described, along with pilot plant operations and detailed descriptions of the plant equipment and its performance. Technical and process problems occurring during initial operations were resolved as encountered. While an inability for achieving acceptable performance levels in the pressurized counterwasher limited success for demonstrating a reliable economical freezing system, several significant objectives were achieved for continued freeze desalting assessment. Follow-on work will include installing a gravity wash column for continued pilot plant operation. (Zielinski - MAXIMA)

WORLD'S FIRST SOLAR POWERED REVERSE OSMOSIS DESALINATION PLANT,
Water Services of America, Inc., Milwaukee, WI.
W. W. Boesch.
Desalination, Vol 41, No 2, May 1982, p 233-237, 5 Fig.

Descriptors: *Desalination, Desalination plants, *Solar energy, Reverse osmosis.

Reliable water production to meet the drinking needs of small communiities using the technologies of seawater reverse osmosis (RO) and solar photovoltaic systems have been demonstrated. The abundance of sunshine in arid areas makes solar RO particularly viable. Reliable system operation without other power source backup supplies has also been demonstrated. A simple DC power arrangement for the complete system was shown to be effective. This demonstration system is the beginning of more and larger solar powered (RO) desalination systems.

STUDIES ON ALKALINE EARTH SULFITES - III(1). TRANSIENT SOLUBILITIES AND PHASE CHANGES OF CALCIUM SULFITE IN SEAWATER,
A. Cohen, M. Zangen, M. Koenigsbuch, and J. M. E. Goldschmidt.
Desalination, Vol 41, No 2, May 1982, p 215-232, 11 Tab, 4 Fig, 27 Ref.

Descriptors: *Desalination, *Sulphite pretreatment, *Seawater, *Calcium compounds, Alkaline earth sulfites, Calcium sulfite, Corrosion, Pretreatment of water.

Calcium sulfite was sufficiently soluble in seawater of various compositions to allow the use of SO sub 2 for pretreatment of seawater (to prevent corrosion and alkaline scale formation) in desalting plants. The solubility of calcium sulfite, prepared by mixing 0.4M solutions of Na sub 2 SO sub 3 and CaCl sub 2, in natural or synthetic seawater decreases with time and does not reach equilibrium for several weeks. Transient molal solubilities, at 25C after 20 min and 24 h, respectively, are 2.9 and 2.2 in natural seawater, 3.9 and 3.4 in 0.7M NaCl solution. This decrease is due to a gradual transformation, by a slow dissolution-recrystallization process, of a metastable phase of crystalline calcium sulfite into a more stable, less soluble, modifi-

cation observed by X-ray crystallography, scanning electron microscopy and thermal analysis. The addition of Na sub 2 SO sub 3 to natural seawater produced solutions strongly supersaturated with respect to calcium sulfite. These remained stable for extended periods, and were only slowly affected by solid calcium sulfite added later.

EFFECT OF RECOVERY ON DESALINATION OF THE BLACK SEA WATER BY REVERSE OSMOSIS,
Higher Inst. of Chemical Technology, Burgas (Bulgaria). Dept. of Water Technology.
I. Dobrevsky, V. Mavrov, and B. Bonev.
Desalination, Vol 41, No 2, May 1982, p 209-214, 2 Tab, 5 Fig, 2 Ref.

Descriptors: Desalination, Membranes, RO, Ultrafiltration, Reverse osmosis, Cellulose acetate, Tubular membranes, Black Sea, Brines, Pretreatment of water.

The effect of fresh water recovery was studied during Black Sea water reverse osmosis (RO) desalination with cellulose acetate tubular membranes. Two different schemes of brine pretreatment before RO were investigated. Ultrafiltration can be applied as an effective alternative method for Black Sea water pretreatment. Up to 30% recovery, the product flux as well as the salt and the specific ionic rejection are all fairly stable. Special experiments showed that in a stable turbulent regime Ca ions removal from Black Sea water before RO with tubular membranes hold out no technological advantages.

CHLORIDE/SULPHATE EXCHANGE OF ANION RESINS, KINETIC INVESTIGATION, VIII. INFLUENCE OF SOME PHYSICO-CHEMICAL PROPERTIES OF THE RESINS,
Istituto di Ricerca sulle Acque, Bari (Italy).
L. Liberti, R. Passino, and D. Petruzzelli.
Desalination, Vol 41, No 2, May 1982, p 199-207, 3 Tab, 4 Fig, 8 Ref.

Descriptors: *Desalination, Kinetics, Physicochemical properties, Chlorides, Sulphates, Chloride/Sulphate exchange, *Anion resins, *Resins.

Experimental exchange rates for C1-/SO4- exchange on strictly comparable anion resisn in 0.0006N solution confirm the unfavorable correlation between kinetics and selectivity. Evaluation of the influence of other physico-chemical properties of the resins (i.e. nature of matrix, type of amine, etc.) seems to support the hypothesis that chemical interactions, and not only diffusional effects, in the resin phase play a leading role on rate control. (Balaban-Boston)

PERFORMANCE EVALUATION AND PROCESS DESIGN OF AN ELECTRODIALYSIS PLANT BY OVERPOTENTIAL MEASUREMENTS,
Istituto di Ricerca sulle Acque, Bari (Italy).
R. Passino, C. Marra, A. Rozzi, and G. Tiravanti.
Desalination, Vol 41, No 2, May 1982, p 181-197, 1 Tab, 6 Fig, 18 Ref.

Descriptors: *Desalination, Desalination plants, *Electrodialysis plant, Membrane processes, Overpotential measurements, Ionics Mark III ED Stack.

The Ionics Mark III ED stack was investigated. The experimental techniques used allowed ED plant performance to be evaluated as a series of elementary subsystems; concentration boundary layer over-potentials were measured at different locations along the membrane flow path. The current interruption technique was used in order to calculate inter-facial concentrations and diffusion boundary layer thickness. The dependence was established of concentration polarization on membrane path length, the last membrane sections were strongly polarized even at relatively low operating current densities. A better ED plant design should make use of sequence of stack sections at different applied voltages.

SHIP-MOUNTED SEAWATER 2500 CU M/D FLASH EVAPORATION PLANT FOR ABU-DHABI. ECONOMICAL DRINKING WATER FOR ARID REGIONS,
Buckau-Walther A.G., Essen (Germany, F.R.). Water Engineering Div.
K. Wangnick.
Desalination, Vol 41, No 2, May 1982, p 171-180, 7 Fig, 1 Tab.

Descriptors: Desalination, Desalination plants, Distillation, Flash evaporation, Ships, Abu-Dhabi, Arabian Gulf, Buckau-Walther(Krupp).

A ship-mounted seawater desalination plant was tranfered to the Water and Electricity Department of the Government of Abu Dhabi on February 6, 1982. This followed a 12-month construction period and two weeks of trials. Named the 'Rumaith', this is the first self-propelled floating seawater desalination plant built fo commercial use. The plant, consisting of a self-propelled pontoon-like hull carrying two centrally positioned desalination units of 1250 cu m each, will supply islands, coastal towns and major construction sites in the United Arab Emirates with drinking water and will also be deployed in the event of breakdown of stationary desalination plants, to provide an emergency water supply and to alleviate plantation water shortages. After handover, the vessel, accepted by German Lloyd for class + 100 A4K, was towed by tug to Abu Dhabi in the Arabian Gulf in 40 days. As general contractor, Buckau-Walther AG had the vessel built by Detlef Hegemann and Co. Industriewerke Unterwesser.

EFFECTS OF SURFACTANTS ON THE HY- PERFILTRATION PERFORMANCE OF DY- NAMIC MEMBRANES,
Clemson Univ., SC. Dept. of Chemistry and Geology.
R. J. Luppino, and H. G. Spencer.
Desalination, Vol 41, No 1, April 1982, p 33-45, 2 Fig, 7 Tab, 15 Ref.

Descriptors: *Desalination, Desalination plants, *Membranes, *Hyperfiltration, Dynamic membranes, *Surfactants, Zirconium oxide-polyacrylate.

The effects of surfactants on the permeability and the rejections of other solutes during hyperfiltration by zirconium oxide-polyuacrylate dynamic membranes on porous stainless steel tubes were investigated. The hyperfiltration performance was dependent on the type of surfactant and in some cases the effect was dependent on pH. The effects are attributable to the presence of surfactants at the feed-membrane interface and interactions with the membrane. Rejection is significantly increased at a small cost in permeability by the presence of an anionic surfactant. Large permeability declines occur when surfactant-membrane interactions are possible.

REVERSE OSMOSIS SEPARATION OF INOR- GANIC SALTS USING POLYVINYLALCOHOL MEMBRANES,
Erlangen-Nuernberg Univ. (Germany, F.R.). Inst. fuer Technische Chemie.
H. N. Chang.
Desalination, Vol 42, No 1, July 1982, p 63-77, 6 Tab, 2 Fig, 27 Ref.

Descriptors: *Desalination, *Membranes, *Reverse osmosis, Separation techniques, Inorganic compounds, Polyvinyl alcohol membrane.

Permeabilities and fluxes of fifty-four mono-, divalent anions and cations of sodium and chloride salts have been tested under experimental conditions of 50 bar and room temperature through asymmetric polyvinylalcohol membranes crosslinked with formaldehyde. The percentage rejections among these salts are: sodium salts of divalent anions (70-80%); chloride salts of divalent cations (30-40%); H sub 2 SO sub 4 (30%); sodium salts of monovalent monoatomic anions, chloride salts of monovalent cations (15-30%); and HCl, HNO sub 3, NaOH, KOH (10-20%). Sodium salts of monovalent polyatomic anions gave higher rejections than those of monovalent monoatomic anions. Higher rejection of divalent anions than that of divalent cations of chloride salts suggests that the membrane surface is negatively charged.

Desalination, Vol 41, No 3, June 1982, p 249-261, 5 Tab, 5 Fig, 22 Ref.

Descriptors: *Desalination, *Ultrafiltration, Membrane processes, *Membranes, Polyelectrolytes, Composite charged membrane, Poly(styrene sulfonate).

To develop a low pressure desalination membrane with fixed ionic charges, use was made of the normally unwanted crosslinking tendency in preparing the polyelectrolyte poly(styrene sulfonate) by sulfonation of polystyrene. After dipcoating a poly(sulfone) or poly(phenylene oxide) ultrafiltration (UF) membrane with a dilute solution of this

polyelectrolyte in water in the presence of some free sulfuric acid and silversulfate, fixation and cross-linking of the coating polymer took place by a heat treatment. Different membrane properties could be obtained by varying the pore size of the supporting UF membranes, and by variation in the coating polymer (M.W. concentration) and sulfuric acid concentration. Fluxes sometimes decline drastically in comparison with the original pure water flux; salt rejection values (at 1.5 g/l NaCl concentration and 0.5 MPa) never are very high (less than or equal to 60% for monovalent anions). The most important potential application for these membranes lies in their nonfouling properties.

A CONSIDERATION ON FLOW DISTRIBUTION IN AN ION EXCHANGE COMPARTMENT WITH SPACER,
Radiation Center of Osaka Prefecture, Osaka (Japan)
H. Miyoshi, T. Fukumoto, and T. Kataoka.
Desalination, Vol 42, No 1, Jul 1982, p 47-55, 2 Tab, 6 Fig, 6 Ref.

Descriptors: *Desalination, Membrane processes, Ion exchange, Eddy constant, Navier-Stokes equation, *Fluid mechanics.

The flow distribution in an ion exchange compartment with a spacer is necessary to analyze the mass transfer in the compartment. An equation on the flow distribution in the compartment was theoretically derived by substituting the eddy viscosity of the spacer to the Navier-Stokes equation. The values of the eddy constant contained in the eddy viscosity were indirectly measured, and an experimental equation for estimating the eddy constant is given.

VERTICAL TUBE FOAM EVAPORATION FOR WATER DESALINATION,
Envirotech-Sephton Development Center, Emeryville, CA.
H. H. Sephton.
Desalination, Vol 42, No 1, July 1982, p 27-35, 4 Fig, 14 Ref.

Descriptors: *Desalination, *Distillation, Vertical tube foam evaporation, Evaporator.

Vertical tube foam evaporation (VTFE) provides a method of enhancing evaporator performance substantially by increasing the brine-side heat transfer coefficient. It reduces the temperature needed to drive evaporation and the energy required; consequently, the evaporation rate of evaporator capacity is increased under constant temperature conditions. VTFE applied to multiple effect evaporators, to evaporate with vapor compression to drive the process and to waste-heat evaporation of aquaious solutions are illustrated by test data obtained with pilot plants operated under realistic process conditions and utilizing full-size distillation tubes.

THE CHANGING FACE OF DESALINATION - A CONSULTING ENGINEER'S VIEWPOINT,
Binnie and Partners, London (England).
F. C. Wood.
Desalination, Vol 42, No 1, July 1982, p 17-25, 3 Tab, 2 Fig, 11 Ref.

Descriptors: *Desalination, Desalination plants, *Distillation, *Reverse osmosis, Solar, *Economic evaluations, Forecasting, Multistage flash.

The present major market for desalting plants will continue to rely mainly upon the proven multistage flash process until local policy dictates a need for resources conservation or the long-term merits of reverse osmosis (RO), as well as its high energy-efficiency, are well established. On the other hand, industrialized, oil-importing countries, with increasing water shortages and environmental contraints, must develop energy-efficient processes for single- and dual-purpose operation as well as improve RO membranes for desalting of seawater. The needs of small-plant users require particular consideration if the simple yet reliable plants which their circumstances demand are to be satisfied. Solar plants are likely to find their initial commercial applications in this market.

TECHNOLOGICAL AND ENVIRONMENTAL ASPECTS OF DESALINATION,
R. S. Silver.
Desalination, Vol 42, No 1, July 1982. p 1-9.

Descriptors: *Desalination, *History, Industrial water social needs, *Social aspects.

The industrial and sociological importance of desalination, and its place in the nexus of chemical engineering are surveyed. The history of its development, particularly in the last two decades, is reviewed, and the risky task of foreseeing the next 20 years in the field is attempted. For this latter task there is a crystal ball provided by the laws of thermodynamics, but unfortunately the crystal view is frequently distorted by inadequate understanding of these principles and their application. A fundamental analysis is given of desalination processes in terms of thermodynamics, demonstrating the interaction between practical necessities and thermodynamic imperatives. It is shown how the implications of this analysis have been confirmed by the history of development, and so suggests confidence in the interpretation for the future. All signals are subject to distortion by noise, and reference is made to the main sources of noise in this subject, which vary from the shrill sounds of the marketplace through the sombre notes of fiscal policies to the cacophony of politics.

SYNTHETIC MEMBRANES: STATE OF THE ART,
Max-Planck-Inst. fuer Biophysik, Frankfurt am Main (Germany, F.R.).
W. Pusch, and A. Walch.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29-Oct. 1, 1980), p 5-20, 2 Tab, 14 Fig, 46 Ref.

Descriptors: *Desalination, Desalination plants, *Membranes, *Review, Reverse osmosis, Electrodialysis.

Synthetic membranes are used for a great variety of separation processes such as dialysis, electrodialysis, hemodialysis and hemofiltration, ultra- and hyperfiltration, and pervaporation, where the process is generally designated according to the applied driving force such as a concentration, electrical potential, or pressure difference, respectively, across the membrane. A great deal of work was spent during the last 25 years for the development of the best possible membranes using almost every available polymeric material. At the beginning of membrane research, natural polymers such as cellulose and cellulose derivatives were essentially employed for the preparation of appropriate membranes such as collodion and cellulose acetate, for instance. These polymeric materials were rediscovered for the preparation of desalination membranes installed into hyperfiltration modules for the production of fresh water from brackish and seawater. In this connection, new membrane structures and configurations were designed besides the common homogeneous flat sheet membrane in order to meet the demands of high flux and high packaging density of a corresponding membrane module. With respect to an improved packaging density, spiral-wound, tubular, capillary, and hollow-fine fiber modules were designed in addition to the classical plate and frame module. Moreover, asymmetric and so-called composite membranes were developed to generate high flux membranes possessing the same selectivity as the corresponding homogeneous ones. Concurrently with the development of new membrane structures and configurations, new polymeric materials such as polyamides, polymides and polybenzimidazolone were cast into membranes improved transport properties and chemical resistivity.

DEVELOPMENT OF NEW MEMBRANES,
Forschungsinstitut Berghof G.m.b.H., Tuebingen (Germany, F.R.).
H. Strathmann.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29-Oct. 1, 1980), p 39-58, 14 Fig, 29 Ref.

Descriptors: *Review, *Desalination, Desalination plants, *Membranes, Hyperfiltration, Ultrafiltration, Polymers, Cellulose acetate, Polysulfone, Polyamide.

Asymmetric membranes made from various polymers, such as cellulose acetate, polysulfone, polyamide, etc. by a phase inversion process are widely used today in ultra- and hyperfiltration. In spite of their good filtration properties, these membranes have certain short-comings as far as their selectivity and chemical stability are concerned. Considerable effort has therefore been spent in recent years to develop new membranes with better separation characteristics and better overall properties tailormade for special applications. For desalination of sea- and brackish waters, e.g., composite membranes with better chemical stability and higher fluxes and salt rejection have been developed. For the treatment of certain industrial effluents, liquid membranes with carrier facilitated transport properties for certain metal ions are available today. Membrane preparation techniques are no longer limited to the phase inversion process; track etching procedures, plasma polymerization and radiation induced grafting are used today to produce membranes for various applications. Recent developments in the preparation techniques of membranes and membrane materials are reviewed.

CONCENTRATION POLARIZATION AND FOULING,
Lund Univ. (Sweden). Food Engineering Div.
E. Matthiasson, and B. Sivik.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29-Oct. 1, 1980), p 59-103, 3 Tab, 7 Fig, 143 Ref.

Descriptors: *Membranes processes, *Polarization, *Desalination, Seawater, Membranes, Fouling.

Concentration polarization is often the reason for the serious limitation of the membrane processes due to its negative influence on the transmembrane flux. Many theoretical studies on this polarization phenomena have resulted in mathematical models for concentration polarization. In most of them, solutions are sought for the coupled nonlinear system of the equations of continuity and motion. Each of these solutions makes use of some assumptions in order to simplify the equations which represent the phenomenon. Different kinds of flow systems have been constructed in order to reduce the concentration polarization. The aim of these flow systems has mainly been to improve the mass transport from the membrane surface back to the bulk solution. Fouling often is a result of concentration polarization, but can also have other reasons. Unveiling the basic mechanisms of fouling attracted little attention until the late seventies, when for example, fouling of an RO seawater desalination membrane could be subdivided into four consecutive steps. Studies of the chemistry and physics of fouling were performed on whey and revealed in close detail some of the responsible phenomena.

ULTRAFILTRATION AT LOW DEGREES OF CONCENTRATION POLARIZATION: TECHNICAL POSSIBILITIES,
Lund Univ. (Sweden). Food Engineering Div.
M. Lopez-Leiva.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29-Oct. 1, 1980), p 115-128, 2 Tab, 9 Fig, 11 Ref.

Descriptors: *Desalination, Desalination plants, *Membranes, Ultrafiltration, *Concentration polarization, Plate-and-frame membrane.

The phenomenon of concentration polarization (CP) produces well known deleterious effects in ultrafiltration (UF), the most important being the many-fold diminishing of trans-membrane flux. Classical methods used to decrease this negative influence have made use of either a turbulent flow or a high shear stress laminar flow past the membrane. In both cases the liquid is recirculated through the UF module until the desired degree of concentration is obtained. The same type of flow can be obtained either by moving the membrane in relation to the liquid or by moving a surface parallel to the membrane. Here the velocity of the fluid across the module is irrelevant and consequently it can be set according to the degree of concentration required. Two modules working with this principle are presented. One of laboratory-scale size is composed of a pair of concentric cylinders of which the inner one, carrying the semipermeable membrane, is rotatable. The other module, of around 0.6-sq m membrane area, is of the rotary 'plate-and-frame' type. Energy consumption curves for each module as well as their performance in the ultrafiltration of BSA solutions and milk are presented.

FOULING OF ULTRAFILTRATION MEMBRANES: LATERAL MIGRATION AND THE PARTICLE TRAJECTORY MODEL,
Rensselaer Polytechnic Inst., Troy, NY. Dept. of Chemical and Environmental Engineering.
G. Green, and G. Belfort.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29-Oct. 1, 1980), p 129-147, 6 Fig, 48 Ref.

Descriptors: *Membranes, *Ultrafiltration, Fouling, Colloids, Lateral migration, *'Flux-paradox' problem.

Lateral migration theory is used both to explain the 'flux-paradox' problem for colloidal suspensions and as part of the standard filtration theory for calculating permeation flux as a function of time. Particle trajectory analysis is used to model the physics of colloidal fouling in tangential flow ultrafiltration. A method is also suggested on how to incorporate trajectory analysis into the standard filtration theory. The theoretical results are compared with experiments from the literature and from the author's laboratory.

EVALUATION OF STATIC MIXERS AS CONVECTION PROMOTERS IN THE ULTRAFILTRATION OF DAIRY LIQUIDS,
Nederlands Inst. voor Zuivelonderzoek, Ede.
J. Hiddink, D. Kloosterboer, and S. Bruin.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29-Oct. 1, 1980), p 149-167, 6 Tab, 6 Fig, 17 Ref

Descriptors: *Membranes, *Ultrafiltration, *Dairy industry, Static mixer, Milk.

The efficiency was determined of various types of static mixer (variants of the Kenics type) for enhancing the permeate flux in ultrafiltration plants. A theoretical analysis of the transport phenomena that occur in the laminar-flow region in a tube divided into two half-cylindrical channels, showed that the mass transfer coefficient increased by a factor 1.95 as compared with that in a cylindrical tube. The increase in permeate flux obtained in the experiments, amounted to a factor 2.9. This extra effect should be attributed to rotation of the liquid and changes in the direction of rotation, caused by the static mixers. At equal energy input levels, approximately equal permeate fluxes were achieved in both the laminar-flow and the turbulent-flow region, whether static mixers were used or not. The types of static mixer tested did little to improve the energy efficiency in ultrafiltration plants under the prevailing conditions.
W84-00695

MEMBRANE PROCESSES IN THE DAIRY INDUSTRY,
Nederlands Inst. voor Zuivelonderzoek, Ede.
R. De Boer, and J. Hiddink.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29-Oct. 1, 1980), p 169-192, 1 Tab, 13 Fig, 44 Ref.

Descriptors: *Membranes, *Ultrafiltration, *Reverse osmosis, Milk, Whey, Cellulose acetate, *Dairy industry.

From the increase in the ultrafiltration (UF) and reverse osmosis (RO) membrane surface, considerable progress has been made in the dairy industry during the last 10 years. This development will continue in the eighties. The increase in energy prices wil favour the development of RO, not only for whey but, due to an increase permeate flux, also for milk. In addition to concentration before transport to centralized plants the manufacture of milk products from concentrated milk will be also of interest. A developing whey protein market for products with 35%, 60% and 80% protein and a more stringent pollution control, which will force the dairy industry to process their whey, will influence th application of UF positively. The use of UF for the manufacture of a variety of cheeses from fresh to semi-hard cheese is a possibility now. An important point in this development is that the manufacturers of equipment offer complete production lines. A by-product of UF is the permeate with its high lactose content, and possibilities for profitable use have recently become available. To achieve a higher permeate flux pretreatment of the starting liquid has to be applied in many cases. Fouling of the membranes is particularly caused by calcium phosphate. Proteins play some role. More research is necessary before these phenomena are fully understood. Not only the pretreatment but also the bacteriological aspects are a specific problem for the dairy industry. Especially in cases of RO at 30C - the maximum process temperature for cellulose acetate membranes - continuous attention to cleaning and disinfection is necessary.
W84-00696

PRODUCTION OF WHEY PROTEIN CONCENTRATES WITH HIGH SOLIDS CONTENT,
Pasilac A/S, Silkeborg (Denmark).
J. Rubin.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29-Oct. 1, 1980), p 193-199, 4 Tab, 3 Fig.

Descriptors: *Ultrafiltration, *Dairy industry, Milk, Membranes, *Whey, Proteins.

Ultrafiltration is very useful in production of whey protein powders. The protein concentrates obtained by this process seldom have a solid content higher than about 20%, and it is very difficult to evaporate, especially concentrates with relatively high protein contents. This means that a large part of the whey protein concentrates produced today is spray dried directly which in turn is costly and may give troubles with e.g. light and bulky powders. At experiments on a DDS 20-cm laboratory module it was possible to concentrate whey protein concentrates with about 80% protein in solids to more than 35% total solids. A number of filtration and ultrafiltration membranes were at temperatures up to 50C and varying pre Using ultrafiltration membranes further g increase in the relative protein content of th centrate. Results obtained on the lab-modul later confirmed on a DDS/Pasilac pilot pla a 7 sq m 30-cm module equipment with G membranes. The pilot plant was operated b batch and in continuous mode. The final c trates could be 'pasteurized' at 66C for 15 s but blocked the pasteurizer at 69C. Spray dr the product using a nozzle atomizer was unc cated and gave a relatively high bulk density resulting powders.

CONCENTRATION OF RAW WHOLE BY REVERSE OSMOSIS AND ITS INFLU ON FAT GLOBULES,
Nederlands Inst. voor Zuivelonderzoek, Ede
R. De Boer, and P. F. C. Nooy.
Desalination, Vol 35, Nos 1/2/3, Decembe (Comprising the Proceedings of the Symposi Membrane Technology in the 80's, Ystad, Sw Sept. 29-Oct. 1, 1980), p 201-211, 5 Tab, 3 F Ref.

Descriptors: *Reverse osmosis, Tubular reve mosis, *Dairy industry, *Milk, Filtration,

Raw whole milk was twofold concentrate tubular reverse osmosis (RO) system. Meth preventing damage being caused to the m globules were investigated. Fat damage - ch by the BDI method and homogenization deg induced particularly by the normal pressure valves. The use of a capillary tube, press removal (dead-end filtration) or cooling of th before the normal pressure relief valve belo prevented damage to the milk fat. This last m can be applied in a continuous process as wel a batch process. The twofold concentrated derived from the various procedures were at 4C during two to three days, no increase i value took place. Cultured butter made fro centrated milk had a higher diacetyl content more sweet and acid flavour (yoghurt-like) control butter, which is probably the outcom higher solids-not-fat content. No rancid o vours could be detected in the butter made concentrated milk, while during cold stora development of off-flavours of an oxidative acter took place. In addition to the product q attention was also paid to the lay-out of installation based on the principle of dead-e tration.
W84-00698

PRODUCTION AND PROPERTIES OF GHURT AND YMER MADE FROM UL FILTRATED MILK,
Statens Forsoegsmejeri, Hilleroed (Denmark)
G. Mogensen.
Desalination, Vol 35, Nos 1/2/3, December (Comprising the Proceedings of the Symposiu Membrane Technology in the 80's, Ystad, Sw Sept 29-Oct 1, 1980), p 213-222, 3 Tab, 7

Descriptors: *Ultrafiltration, *Dairy ind Milk, Yoghurt, Ymer.

Yoghurt and Ymer are examples of ferm products which are concentrated in solids n (SNF). Ymer is a Danish dairy product wh heavily concentrated. According to Danish le tion it must contain at least 6% milk protein a least 11% SNF. Originally this concentration achieved by draining off 50% whey after ferm tion. The development of ultrafiltration (UF) industrial scale opened new possibilities to tate standardization of SNF, increase product and rationalize the production. The chemical position of ymer made from ultrafiltrated differs, however that prepared in the tradit way. Presumably due to the increased conte calcium and phosphorus, UF-ymer is liable t velop a brittle consistency just as the flavo changed unfavourably. Research has shown the retention of calcium and phosphorus is aff by the heat treatment of the milk prior to UF

perature at which the milk is ultrafiltrated. fluence on product consistency is rather ble and the small decrease in calcium reten- ower filtration temperature could not com- for the decrease in filtration capacity. Be- f the changed chemical composition of the er, the manufacturing technology has to be d.

E SCALE DEW COLLECTION AS A CE OF FRESH WATER SUPPLY,
Univ., Gainesville. Dept. of Mechanical ering.
Rajvanshi.
nation, Vol 36, No 3, March 1981, p 299-306, 2 Tab, 13 Ref.

ptors: *Water supply, *Condensation, Pota- ter, *Dew, Moisture.

A scheme for large-scale dew collection as a source of fresh water supply is outlined. The scheme envisages bringing cold seawater (5C) from about 500 meters depth and about 5 km from the shore, in 4, 1.22-m diam plastic pipes. It then passes through a heat exchanger field with an area of 129,000 cu m (1,390,000 sq ft) where it condenses 643 cu m of dew over the 24-hour period. The pumping of seawater from the sea and through the field is accomplished by three 200-kW wind machines. Technical and economical feasibility of the scheme is analyzed and the possibility of marine culture as a source of food is explored. The present scheme is economically not feasible as compared to a reverse osmosis facility of equivalent capacity.

GROUNDWATER SPRINGS TO CAPE VERDES' AID.
World Water, Vol 5, No 12, p 32-33, December, 1982.

Descriptors: Water resources development, *Groundwater, *Developing countries, *Cape Verde, Faja Tunnel, Tunnels, Water distribution, Wells.

Groundwater supplies are being developed in the Cape Verde archipelago, which has virtually no surface waters and is subject to severe droughts. In addition to many wells being drilled, the 2200 m Faja tunnel, scheduled for commissioning in 1985, will carry groundwater by gravity flow from the foot of Monte Gordo to an agricultural area. Electrical and hand pumps are being used. Two wells equipped with wind-powered generations have been installed. (Cassar-FRC)

3D. Conservation In Domestic and Municipal Use

WATER MANAGEMENT INITIATIVES IN THE COMMONWEALTH,
G. M. Lovejoy, III.
Water/Engineering and Management, Vol 130, No 3, p 30-32, March, 1983. 2 Tab.

Descriptors: *Water management, *Water shortage, *Industrial water, *Massachusetts, Water supply, Water demand, Financing, Water conservation, Legislation, Municipal water, Prices, Water rates, Water distribution, Water treatment.

Although Massachusetts has an average annual rainfall of 46 inches, water shortages occur in some sections of the state during dry periods as a result of mismanagement. A comprehensive water management and protection bond program, Chapter 286 of the Acts of 1982, signed by the governor on July 10, is designed to expand current programs and create new ones. Most of the programs are matching programs. All communities must devise a comprehensive water resource management plan. In case of water emergency, a community applies to the state for Chapter 40 approval, which provides powers to enforce water conservation measures, giving priority to water for drinking and fire protection at the expense of manufacturing. Of the total $357.5 million program, $205 million is allocated to publicly owned wastewater treatment facilities and sewers and $60 million to leak detection and rehabilitation of water supply systems. Water management methods for several of the state's communities include increased water rates and use of a flat rate instead of block rate. As a result, industry has initiated water conservation procedures. (Cassar-FRC)

SUMMARY REPORT ON DROUGHT PLANNING BY COMMUNITY WATER SYSTEMS.
New York State Dept. of Health, Albany. Bureau of Public Water Supply Protection.
April 1982. 33 p, 5 Fig, 1 Tab, 4 Append.

Descriptors: *Drought, *Water deficit, *Water shortage, *Urban watersheds, *Reservoir storage, *Water supply, Water level recorders, Water table decline, Water table fluctuations, Water conservtion, Planning, Resources development.

Precipitation during the summer and fall of 1980 in the Southeast area of New York State was substantially below normal and resulted in what has become known as the drought of 1980-81. Total precipitation for 1980 averaged 36.86 in., a deficit of about 8 in. from the mean of 44.93 in. Subsequent studies found that emergency sources were, in general, readily available for most community water systems with the exception of the New York City system and systems in Westchester and Rockland Counties. In addition, New York City made significant conservation efforts which resulted in an overall reduction in water usage of more 200 mgd. Westchester County, in which 79% of the population depends on New York City's reservoir system, has very few usable emergency sources and, therefore, must rely primarily on reducing water usage during periods of drought. In Rockland County, excessive releases from Lake DeForest can be prevented by new opeating regulations. Recommendations for suppliers of water are: (1) water source level monitoring; (2) reservoir volume measurements; (3) new source development; (4) metering of community water systems; (5) emergency source sampling program; (6) emergency source construction or rehabilitation; and (7) emergency equipment stockpile improvement. Additional recommendations are made for regional water management. (Garrison-Omniplan)

REUSING COOLING WATER IN AN ELECTRIC POWER PLANT,
Burns and McDonnell, Kansas City, MO.
W. P. Grobmyer, W. J. Wilson, J. F. Hancock, and M. L. Kurtz.
Journal of the American Water Works Association, Vol 75, No 3, p 119-123, March, 1983. 3 Fig, 2 Tab.

Descriptors: *Cooling water, *Industrial wastewater, *Zero discharge, *Water reuse, Powerplants, Wastewater treatment, Water conservation, Landfills, Deerhaven Station, FLorida, Water quality control, Dissolved solids, Brines.

The Deerhaven fossil fuel-fired generating station, near Gainesville, Florida, has achieved zero waste discharge by reusing cooling water treated by a front-end process. This uses a two-stage lime-soda softening process. In the first stage lime is used to precipitate bicarbonate alkalinity, Mg, and silica at a pH of 11.2-11.4. In the second stage soda ash and carbon dioxide are added to remove Ca and remaining silica. Sludge is treated with potato starch and polymer. The front-end method was chosen after a side-stream technique proved infeasible. During the first year of operation the average effluent contained 15 mg per liter Ca as CaCO3 and 2-3 mg per liter silica. This effluent quality allows 50 cycles of concentration and reuse. Liquid waste is treated in a vapor compression evaporator and spray dryer, and the residue is placed in a clay-lined landfill. The zero discharge policy has decreased the quantity of groundwater taken from the Floridan Aquifer and has reduced damage to the environment downstream of the former waste discharge. (Cassar-FRC)

Descriptors: *Food processing industry, *Food-processing wastes, *Industrial wastewater, Indus-

trial water, Reclaimed water, Wastewater renovation, Process water, Recirculated water, Water use, *Water reuse, Wastewater, Health effects.

The potential for water reuse and recycle in each of the major water-using segments of the food industry was evaluated, and projections made for the 1985 and 2000 year water withdrawals in each of the segments with the implementation of water reuse and recycle. The geographic potential for water reuse and recycle was determined in each of the Water Resource Council subregions by past water withdrawals for food processing water availability and types of food processing within the subregion. Product contamination and its impact on the health of the consumer are the major concern in water reuse and recycle in food processing. The potential for reducing product contamination discussed in the report involves the development of water quality criteria for water reuse and recycle in food processing and the evaluation of suitable products and processing operations which will eliminate or reduce contamination resulting from water reuse and recycle prior to final processing operations.

CROP YIELD AS AFFECTED BY SPATIAL VARIATIONS OF SOIL AND IRRIGATION,
Arizona Univ., Tucson. Dept. of Soils, Water and Engineering.
A. W. Warrick, and W. R. Gardner.
Water Resources Research, Vol 19, No 1, p 181-186, February, 1983. 4 Fig, 2 Tab, 21 Ref.

Descriptors: *Crop yield, *Irrigation, *Soil properties, Spatial variation, Monte Carlo method, Costs.

Crop yield is calculated for varying uniformities of seasonal available water. The variation is a consequence of both irrigation and soil heterogeneity. Analytical expressions and Monte Carlo simulations are used to calculate yields for an assumed linear response function. A comprehensive table from the Monte Carlo simulations includes results for 50, 100, and 200% of the water necessary for maximum yield. These are collated with five uniformities and three levels of effective available water. Uniformities of water are expressed as coefficients of variation ranging from 0 to 2. Variations in either irrigation or soil uniformity change the results, but irrigation uniformity is likely the more important, especially for surface systems. The effect of taking the two distributions--for irrigation and soil-- to be correlated does not affect results greatly. When only cost of water is considered, the marginal rate of return is verified to be a maximum for smaller operations. (Author abstract)

SMALL HYDRO MAY HELP CZECHOSLOVAKIA'S NEEDS,
International Water Power and Dam Construction, Vol 35, No 2, p 45-56, February, 1983.

Descriptors: *Powerplants, *Hydroelectric power, *Water resources development, *Planning, Czechoslovakia, Energy, Economic aspects, Water demand.

A survey conducted by the Czechoslovak Ministry of Energy has determined that 11 TWh could be generated if all the feasible small scale hydro sites were to be exploited in the country. However, the planning difficulties of constructing and equipping these stations may prove to be too large. Currently small-scale hydro stations provide 3.7 GWh of energy every year to the Czechoslovakian economy, accounting for about 5% of all the country's hydropower output. The basic principles of long-term mini-hydro development were approved by the government in 1979, and practical strategies have since been detailed in a number of government decrees, calling on local councils to investigate the options of water power resources within the area, with particular reference to locations where existing dams, reservoirs and weirs favor the installation of mini-hydro equipment. Credit terms made available are highly favorable for new developments. Even so, little has been done so far. Many local councils feel that the yield of mini hydro stations is so modest, and the profit so small, that it is not worth their while to invest time or capital on the sites. Others are wary of the duties involved. The most important deterrent is that there are no standard ranges of turbine or generator units readily available on the Czechoslovak market. The units now operating are invariably one-off designs which require the attention of a local enthusiast to continue functioning. (Baker-FRC)

HYDROPOWER PROSPECTS FOR SPAIN,
International Water Power and Dam Construction, Vol 35, No 2, February, p 24-27, 1983. 4 Fig, 3 Tab.

Descriptors: *Hydroelectric power, *Water resources development, *Dam construction, *Planning, Spain, Floods, Drought.

The first socialist government in Spain for more than 40 years is making plans to accelerate its water control and hydropower program and strengthen the plans it inherited from the previous leadership to extend irrigated areas and invest more capital in dam building. A greater use of water resources and a substantial increase in Spain's new Plain Hidrologico Nacional covering the period between 1982 and 1986 are part of the plan. The drought over the past 3 years indicated severe need for water reserve development in the southern part of the country. The most urgent sections of the current plan deal with the south of Spain, the Guadalquivir river basin, and area of the Guadina river. The general outline of the plan is that Spanish territories should yield another 14,000 cubic meters/year of water to be regulated, which would mean that some 60% of the natural water resources would be controlled. Dam reservoir capacity would have to be raised from the present 46065 cubic hm to 76000 cubic hm. Much work is needed in the mountainous areas of the Iberian Peninsula to ensure that drought conditions can be withstood, and to limit the flash floods, which caused worse damage in the Pyrenees than the Valencia region. An 88-square-mile segment of the White River valley contains an unconfined sand and gravel aquifer ranging-from a featheredge zero, to 120 feet in saturated thickness. Hydraulic conductivity is 340 feet per day, and transmissivity is as much as 35,000 square feet per day. The aquifer, recharged primarily by precipitation, gains same recharge through interbedded till and outwash boundaries and through losing streams. A two-dimensional digital model was used to simulate the steady-state ground-water flow system. Sensitivity analyses tested the reaction of the model to adjustments in hydraulic conductivity, steam bed leakance, and recharge. Simulated pumpage of 20-, 66-, and 122-million gallons per day reduced streamflow by 5, 15, and 30%, respectively. A real drawdown did not exceed 25 feet. Ground water was a calcium bicarbonate type having a median pH of 7.1, a mean alkalinity of 240 milligrams per liter, a mean hardness of 280 milligrams per liter, a mean dissolved oxygen concentration of 2.2 milligrams per liter, a mean redox potential of +347 millivolts, and a mean dissolved-solids concentration of 366 milligrams per liter. Iron and manganese concentrations exceeded National Drinking Water Regulations in 15 and 49% of the analyses, respectively. Temperature and concentration of dissolved organic carbon varied seasonally. Dissolved carbon and manganese varied with seasonally. Dissolved carbon and manganese varied with differing boundary material, till and bedrock. (USGS)

PRELIMINARY EVALUATION OF THE POTENTIAL FOR ARTIFICIAL GROUNDWATER RECHARGE IN EASTERN SAN JOAQUIN COUNTY, CALIFORNIA,
Geological Survey, Sacramento, CA. Water Resources Div.
H. T. Mitten.
USGS Open-File Report 82-123, July 1982. 31 p, 13 Fig, 2 Tab, 19 Ref.

Descriptors: *Artificial recharge, *Groundwater recharge, Recharge, *California, San Joaquin Valley, Central Valley, San Joaquin County.

In response to increasing demand on water supplies and declining water levels in San Joaquin County, the U. S. Geological Survey, in cooperation with the San Joaquin County Flood Control and Water Conservation District, is evaluating the potential for artificially recharging the aquifer system in eastern San Joaquin County, California. Through a well canvass and analyses of existing data on geology, soils, and drillers logs, this study (phase one of three phases) resulted in identification of 20 sites for exploratory test drilling in areas potentially favorable for artificial recharge. Ten of the sites are in areas adjacent to the Mokelumne River, six are in areas adjacent to the Calaveras River and Mormon Slough, and four are north of Littlejohns Creek. (USGS)

SIMULATIONS OF FLOW IN A GLACIAL OUTWASH AQUIFER, SOUTHERN FRANKLIN COUNTY, OHIO,
Geological Survey, Columbus, OH. Water Resources Div.
A. C. Razem.
USGS Water-Resources Investigations Report 83-4022, 1983. 32 p, 6 Fig, 2 Tab, 4 Ref.

Descriptors: *Computer models, Aquifer characteristics, *Glacial aquifers, Pumping, Groundwater recharge, Surface-groundwater relations, *Drawdown, *Ohio, *Columbus, Middle Scioto River Valley.

A two-dimensional, finite-difference model is used to simulate transient flow conditions in a glacial outwash aquifer in southern Franklin County, Ohio. The model was calibrated by matching observed and simulated water-level changes for December 1977 through March 1980. Drawdowns for three different hypothetical pumping rates are simulated with the calibrated flow model. An increase in the pumping rate from the steady-state rate of 10 cubic feet per second to 48 cubic feet per second results in water-level declines of 10 to 20 feet near the area of the pumping wells. Declines of 20 to 40 feet result when the pumping rate is increased to 70 cubic feet per second, and a simulated pumping well goes dry when the combined pumping is increased to 94 cubic feet per second. For the first two cases, steady-flow conditions are reached after 12 years of pumping; infiltration through riverbeds accounts for 28 to 33% of the pumpage.

USGS Water-Resources Investigations 82-4045, 1983. 45 p, 12 Fig, 6 Tab, 48 Ref.

Descriptors: *Groundwater, Model studies, Surface groundwater relationships, *Sewers, Simulation, *Computer models, Long Island, *New York.

A computer simulation of Long Island's regional groundwater system has been used to evaluate the effects that new-installed sewers will have on ground-water levels. Results indicate maximum water-table decliners of as much as up to 18 feet in central Nassau County and about 9 feet in Suffolk County. Total stream base flows and freshwater outflow to the south shore bay system will decrease by 22%. The regional scale of the model does not permit detailed predictions for individual streams. To quantify the effects of lowered ground-water levels on individual streams, two fine-scale sub-regional models have been designed. This report, the first in a three-part series describing the simulated effects of sewers in southern Nassau and southwestern Suffolk Counties, presents the hydrogeologic setting, pertinent literature, modeling strategy, subregional model design, and the results obtained to date from the regional ground-water model. The regional model results described will be used in the later reports to generate flux boundary conditions for the subregional models. (USGS)

4D. Watershed Protection

TO REMEDY EROSION: CONTOUR SPREADER-SEEPAGE FURROWS,
J. Hindson.
Environmental Conservation, Vol 9, No 3, p 251, 1982.

Descriptors: *Erosion control, *Storm runoff, Groundwater supplies, Groundwater development, Erosion, Contour spreader-seepage furrows, Contour terracing, Contours.

The use of contour spreader-seepage furrows to control the flow of storm water down a slope is described. A cut is made in the earthen slope, thus allowing a place for the storm water to collect. This cut is spread along the top of the slope, allowing the collected water to likewise spread out for 100-200 meters before being sent over the edge of the cut and on down the slope. The soil taken from the slope to make the cut is spread on top of the slope on the downhill side, where the water will eventually begin to trickle over the edge. The spreading effect on concentrated storm-water runoff is probably the largest single benefit of the contour spreader-seepage furrow program. The other major benefit is the water storage and infiltration aspect of the work. The groundwater (water table) will inevitably benefit very considerably, especially in deep absorbent soils. This means that erstwhile springs could begin to flow again and wells and water holes would not dry up. In areas needing improved groundwater supplies, CSFs may provide the answer so long as there is periodic surface storm water runoff which would otherwise run to waste. (Baker-FRC)

5. WATER QUALITY MANAGEMENT AND PROTECTION

5A. Identification Of Pollutants

A SIMPLE FIELD TEST FOR THE DETECTION OF FAECAL POLLUTION IN DRINKING WATER,
Defence Research and Development Establishment, Gwalior (India). Div. of Microbiology.
K. S. Manja, M. S. Maurya, and K. M. Rao.
Bulletin of the World Health Organization, Vol 60, No 5, p 797-801, 1982. 1 Fig, 3 Tab, 15 Ref.

Descriptors: *Water analysis, *Water quality control, *Feces, Drinking water, Pollutant identification, Coliforms, Hydrogen sulfide, Human disease, Hepatitis.

A very simple method is presented for assessment of contamination in drinking water based on the detection of hydrogen sulfide-producing organisms. This new test was found to be reliable, simple to perform, and required few facilities. The concentrated medium used in the test contained 20 g of peptone, 1.5 g of dipotassium hydrogen phosphate, 0.75 g of ferris ammonium citrate, 1 g of sodium thiosulfate, 1 ml of Teepol, and 50 ml of water. Aliquots of 1 ml of the concentrated medium were absorbed onto folded tissue paper which was placed in a McCartney bottle, sterilized, and dried at 50C under sterile conditions. The water samples to be screened for faecal pollution were placed in the bottles, up to a pre-calibrated mark (20 ml) and allowed to stand at ambient temperature (30-37C). Fecal pollution is indicated if the contents of the bottle turn black within 12-18 hours, in which case the water was graded as unfit for consumption. This test should be useful for screening rural water supplies and for large-scale screening of urban water supplies where resources, time, manpower, and laboratory facilities are limited. (Baker-FRC)

Descriptors: *Surface waters, *Viruses, *Public health, Germany, Berlin, Human disease, Pollutant identification, Water quality, Drinking water, Water treatment, Disinfection, Enteroviruses, Coxsackie virus.

From 1970 to 1979 a total of 1908 surface water samples from 30 sampling points were evaluated for determination of the concentration of viruses. The rate of virus isolation ranged from 8 to 92%, with a mean of 20%. There were considerable differences in isolation rate among the sampling points, and the rate for any particular point varied from year to year. The mean value of virus concentration was 2.7 cytopathogenic units per liter, while the maximum was 22.1 CU/liter. Viruses seen during the 10 year period included poliovirus types 1, 2, and 3, echovirus types 6, 11, and 30, and coxsackievirus B 3 and B 5; echovirus 7 and 24, coxsackievirus B 1, and adenovirus 5 were seen occasionally. The findings reflected the high level of use of surface waters in the German Democratic Republic. Where water is intended for human use such as drinking or recreation, reasonable safety measures such as water treatment and disinfection should be taken to ensure that the level of viral contamination is within the permissible limits. RADIUM-224 IN NATURAL WATERS MEASURED BY GAMMA-RAY SPECTROMETRY,
Chevron USA, Inc., New Orleans, LA.
R. J. Eisinger, P. T. King, and W. S. Moore.
Analytica Chimica Acta, Vol 144, p 277-281, 1982. 1 Fig, 1 Tab, 10 Ref.

Descriptors: *Pollutant identification, *Radon, *Isotopic tracers, *Spectrophotometry, Radioisotopes, Isotope studies, Estuaries, Separation techniques, Groundwater, Fate of pollutants.

A method based on germanium (lithium) gamma-ray spectrometry was applied to the determination of radon 224 in natural waters. The radon radioisotope is removed from several hundred liters of water by preconcentration onto manganese dioxide-impregnated acrylic fibers. The acrylic fibers are leached with water, and the radium is coprecipitated with barium sulfate. The gamma-ray activity is counted so that the activity ratios among the 224, 226, and 228 radon isotopes can be determined. Concentrations are calculated by using the radon 226 concentration determined on a small separate sample. The method was applied to the determination of radon in groundwater and estuarine and continental shelf waters. (Geiger-FRC)

POTENTIAL HAZARDS OF NITRATE AND FLUORIDE IN UNDERGROUND WATER,
R.B.S. Coll., Bichpuri (India). Dept. of Agricultural Chemistry and Soil Science.
B. Pal.
Water Research, Vol 17, No 3, p 353-354, March, 1983. 2 Tab, 14 Ref.

Descriptors: *Nitrates, *Fluorides, *Water quality standards, Groundwater, Water analysis, Agra, *India, Saline water, Conductivity, Drinking water, Irrigation water, Pollutant identification.

A series of 113 groundwater samples collected from wells in the semiarid tract of Agra, India, contained up to 148.8 mg per liter nitrate and up to 18.5 mg per liter fluoride. Nitrate and fluoride levels increased with increasing conductivity from an average of 18.1 mg per liter nitrate and 0.6 mg per liter fluoride at 1-2 mmhos per cm to an average of 100.6 mg per liter nitrate and 10.1 mg per liter fluoride at >15 mmhos per cm. Fluoride levels exceeded 1 mg per liter (drinking water standard) in 49% of samples and exceeded 10 mg per liter (safe limit for crops) in 23.1% of samples. Nitrate levels exceeded the 10 mg per liter standard for drinking water in 86.6% of samples and exceeded 45 mg per liter (International Standards for Drinking Water) in 40% of samples. (Cassar-FRC)

DETERMINATION OF TRIAZINES IN WATER BY GC AND LC,
Vysoka Skola Chemicko-Technologicka, Prague (Czechoslovakia). Dept. of Analytical Chemistry.
M. Popl, Z. Voznakova, and V. Tatar.
Journal of Chromatographic Science, Vol 21, No 1, p 39-42, 1983. 5 Fig, 2 Tab, 13 Ref.

Descriptors: *Pollutant identification, *Herbicides, *Gas-liquid chromatography, *Triazine pesticides, *Sorption, Pesticides, Separation techniques, Chromatography, Gas chromatography, Water analysis.

A new method was formulated for the chromatographic determination of trace amounts of s-triazine-type herbicides in water. Model water samples were prepared by introducing a volume of the triazine standard in methanol, at concentrations ranging from 200 to 4000 ppm, into 50 milliliters of distilled water. After preconcentration by sorption on a macroporous polymer sorbent and desorption with acetone, s-triazines are determined in the desorbate by gas or liquid chromatography. The s-triazines in water may be detected at the 0.1 ppb level by use of gas-liquid chromatography with a nitrogen-phosphorus detector, or at the ppb level by liquid chromatography with an ultraviolet detector. Recovery from the preconcentration step is virtually complete and analysis takes no more than 1.5 hr. (Geiger-FRC)

STANDARD PLATE COUNT: A COMPARISON OF POUR PLATE AND SPREAD PLATE METHODS,
California Water Service Co., San Jose.
R. H. Taylor, M. J. Allen, and E. E. Geldreich.
Journal of the American Water Works Association, Vol 75, No 1, p 35-37, January, 1983. 1 Fig, 4 Tab, 20 Ref.

Descriptors: *Pollutant identification, *Heterotrophic bacteria, *Bacterial analysis, *Culturing techniques, Aquatic bacteria, Water analysis, Statistical methods, Bacteria.

Evidence from the literature is presented which shows that the standard pour plate procedure recovers only a very low percentage of the total bacterial population present in a water sample. In a long-term study involving routine sampling of dead-end water mains in the Cincinnati, Ohio distribution system, the spread plate and pour plate procedures of bacterial recovery were compared. Of the 613 samples collected, 571 yielded acceptable bacterial counts by both methods. Statistical analysis of test efficiency showed that the spread plate procedure was more precise and more accurate than the pour plate procedure for enumerating heterotrophic plate count population. The spread plate counts consistently decreased as chlorine levels increased, whereas pour plate results were not as consistent through the entire range of free chlorine residuals. While both the spread plate and pour plate procedures offer distinct advantages over the current standard method, analysts must continue to do comparative, parallel testing until they are included in a future edition of Standard Methods. TRACE ELEMENT ANALYSIS OF GROUNDWATER: COMPARISON OF PROTON-INDUCED X-RAY EMISSION (PIXE) WITH ATOMIC ABSORPTION ANALYSIS (AA),
Rutgers - The State Univ., New Brunswick, NJ. Dept. of Chemistry.
G. S. Hall.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-136795, Price codes: A03 in paper copy, A01 in microfiche. Center for Coastal and Environmental Studies Completion Report, July 1983. 22 p, 5 Fig, 3 Tab, 13 Ref. OWRT A-064-NJ(1), 14-34-0001-1132.

Descriptors: Heavy metals, *Groundwater pollution, Chelating agents, X-rays, *Trace elements, *Atomic absorption spectroscopy, *Proton-induced x-ray emission(PIXE).

A simple, rapid, sensitive, accurate, and multielemental analytical method was developed for trace element analysis of groundwater. The method incorporated preconcentration of the water sample with sodium dibenzyldithiocarbamate (NaDBDTC) and was followed by quantitative analysis using external beam proton-induced X-ray emission (PIXE). The emphasis was on quantitative analysis of the elements on the EPA priority pollutant list that included Sb, Cu, Se, Ag, Th, Ni, Zn, Pb, As, Cd, and Hg. The method is particularly attractive for PIXE analysis because akali, akaline, and halogen elements were not complexed. The detection limits for the method were in the 50-60 parts per trillion range using a 6 minute proton irradiation. PIXE was compared with atomic absorption in terms of cost, sensitivity, accuracy, speed of analysis, and precision. It was found that the PIXE method was superior in all cases except for accuracy, in which the method was accurate within 10%.

5B. Sources Of Pollution

DISSIPATION OF MASSIVE QUANTITIES OF 2,4-D AND 2,4,5-T N-BUTYL ESTERS IN FIELD MINI-LYSIMETERS,
Washington State Univ., Pullman. Dept. of Agronomy and Soils.
J. T. Majka, H. H. Cheng, and T. J. Muzik.

Journal of Environmental Quality, Vol 11, No 4, p 645-649, October-December, 1982. 4 Fig, 3 Tab, 13 Ref.

Descriptors: *Herbicides, *Waste disposal, *Chemical wastes, Degradation, Fate of pollutants, Industrial wastes, 2,4-D, 2,4,5-T, Revegetation, Infiltration.

The fate of large quantities of the herbicides 2,4-D and 2,4,5-T n-butyl esters on three soils was studied from December 1976 to April 1979 in minilysimeters located in Pullman, Washington. The esters were applied in a 1:1 mixture at the rates of 560 or 2800 kg per ha to simulate an accidental spill from damaged drums or from disposal of industrial wastes. Soils were: Washington silt loam with pH 5.5, Wyoming clay loam with pH 7.6, and Mississippi sandy loam with pH 4.7. At the lower application rate, both esters dissipated to <1% of the initial concentration in the surface layer by the end of the experiment in the Washington and Wyoming soils; little dissipation of either ester took place in the Mississippi soil. At the higher application rate in all soils 2,4-D concentrations in the soil surface layer decreased slightly, and 2,4,5-T concentrations changed negligibly. Some downward migration of the herbicides from the surface layer to the 5-10 cm deep layer was evident. At the end of the experiment revegetation was noticeable only on the Washington and Wyoming soils at the lower application rate. (Cassar-FRC)

LABORATORY STUDY OF SULFURIC ACID SPILL CHARACTERISTICS PERTAINING TO MARITIME ACCIDENTS,
Brookhaven National Lab., Upton, NY. Dept. of Energy and Environment.
I. N. Tang, W. T. Wong, H. R. Munkelwitz, and M. F. Flessner.
Environmental Science and Technology, Vol 16, No 9, p 587-593, 1982. 8 Fig, 1 Tab, 15 Ref.

Descriptors: *Water pollution sources, *Acids, *Accidents, Ships, Marine environment, Sulfuric acid.

Several acid-spill scenarios are briefly described; they were designed to simulate the two most important types of accidental acid spills reported. In the first type the convective mixing of concentrated sulfuric acid with water is shown to be governed by the buoyancy force arising from changes in acid concentration and released heat of dilution. In the second type, experiments with oleums have resulted in the formation of dense clouds of acid aerosols well within the respirable particle size range. The first type can be adequately described by a mathematical model, taking into account the variation of the buoyancy force arising from changes in acid concentration and liberated heat of dilution. A value of 0.21 is determined to be the entrainment parameter for the sulfuric acid-water system. For the second type a conservative estimate of less than 0.1% is obtained to represent the amount of airborne acid under most accident conditions. The fraction of airborne acid, however, decreases very rapidly with increasing release depth below the water surface. The acid aerosols exhibit a well-defined lognormal particle size distribution, with peak diameter varying from 0.1 to 0.6 micrometers depending upon release depths. Caution should be exercised when extrapolating these data to larger spills. (Baker-FRC)

SALMONELLA SPECIES AND SEROTYPES ISOLATED FROM FARM ANIMALS, ANIMAL FEED, SEWAGE, AND SLUDGE IN SAUDI ARABIA,
American Univ., Beirut (Lebanon). Dept. of Microbiology.
N. H. Nabbut, E. K. Barbour, and H. M. Al-Nakhli.
Bulletin of the World Health Organization, Vol 60, No 5, p 803-807, 1982. 2 Tab, 12 Ref.

Descriptors: *Salmonella, *Sludge, *Sewage bacteria, Land disposal, Saudi Arabia, Manure, Bacteria, Human disease, Public health, Epidemiology, Animal diseases

The isolations of salmonellae from farm animals, animal feed, sewage, and sludge in Saudi Arabia during 1977-1980 are reported. A total of 264 salmonellae representing 65 different species and serotypes were isolated for the first time in that country. The six most frequently isolated Salmonella species or serotypes were: livingstone, concord, 'S. schottmuelleri' (invalid), lille, S. typhimurium, and cerro. Of 61 samples of sewage, 37 were positive for Salmonella; 22 of 47 sludge samples were positive. The isolation of 30 different Salmonella species and serotypes from sewage and 11 from sludge indicates that sewage and sludge play a role in the dissemination of salmonellae in the environment and possibly to man and animals. This dissemination would be more significant if inadequately treated sewage effluents and sludges were used for the irrigation of crops or as soil conditioners. Sewage may be an important indirect source of salmonella infection in animals. Cases of salmonellosis in cattle may result from the application of sewage and cattle slurry to land, but it is difficult to tell how easily cattle grazing on contaminated pastures might become infected. RELEASE OF METHYL MERCURY FROM SEDIMENTS: EFFECTS OF MERCURY CONCENTRATION, LOW TEMPERATURE, AND NUTRIENT ADDITION,
Manitoba Univ., Winnipeg. Dept. of Microbiology
D. R. Wright, and R. D. Hamilton.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 39, No 11, p 1459-1466, 1982. 9 Fig, 38 Ref.

Descriptors: *Methylmercury, *Mercury, *Sediments, Lake sediments, River sediments, Microorganisms, Nutrients, Temperature effects, Biomethylation.

Methyl mercury release from unpolluted, mercury polluted, and mercury enriched lake and river sediments was studied using a flow-through system in plexiglass 'microbasins'. The release of methyl mercury as a function of time from Clay Lake and Wabigoon River mercury-laden sediments characteristically demonstrated a lag during the first week, an increase to a maximum at about 4 weeks followed by a decrease to a steady lower level related to mercury concentration. Production of methyl mercury ranged up to 3.3 micrograms/sq m/day increasing with increasing mercury content as if following saturation kinetics. It leveled off when mercury content was 15-20 micrograms Hg/g. An equilibrium between methylating and demethylating mechanisms is suggested. Release at 4C was 50-70% of that at 20 degrees, suggesting that in polluted Canadian lakes production in winter may be half the total for the year. Increased methyl mercury release was noted when tryptic soy broth was added to sediments at 0.06 to 0.25 g/cubic dm, and very marked increases when added to the water flow at 35 mg/l, suggesting an effect at the sediment-water interface. (Baker-FRC)

LEACHING CHARACTERISTICS OF LIGNITE ASH,
Wyoming Univ., Laramie. Dept. of Civil Engineering.
M. J. Humenick, M. Lang, and K. F. Jackson.
Journal of the Water Pollution Control Federation, Vol 55, No 3:1, p 310-316, March, 1983. 2 Fig, 4 Tab, 14 Ref.

Descriptors: *Groundwater pollution, *Coal gasification, *Leaching, *Ash, Trace metals, Groundwater, Texas, Water pollution control, Sulfates, Calcium, Temperature effects, Aluminum, Arsenic, Boron, Phosphorus, Selenium, Silicon, Zinc.

Contaminants generated by water influx into burn cavities resulting from in situ coal gasification and the subsequent leaching of materials from residual ash are considered. The scope of work included a laboratory study of solubility effects, ash temperature, water temperature, lignite composition, and ash mineralogy. Lignite samples were obtained from three Texas sites. Ash content of the samples varied by more than a factor of three, whe mineral composition of ash varied with con temperature and source of lignite. The ma released to groundwater during leaching w cium and sulfate. Hydroxide seemed to be r in lesser quantities than when leaching as western coals. Leaching at 20C indicated and sulfate release to be proportional amount of these constituents in the ash, leaching at 80C exhibited no effect of ash co tion on calcium and sulfate release. Rel material at 80C was less than that at 20, inc that additional material can be released to g water over time as the surroundings coo release of sparingly soluble material is rea predicted by ionic equilibrium models. Of trace elements tested for in leachate sample aluminum, arsenic, boron, phosphorus, se silicon, and zinc were found in concent having some significance. Restoration of g water contaminated because of ash leaching achieved by withdrawal of cavity water. FRC)

OXYGEN DEMAND OF TACONITE INGS,
Texas Tech Univ., Lubbock. Dept. of Civi neering.
R. H. Plumb, and G. F. Lee.
Journal of the Water Pollution Control Fede Vol 55, No 3, p 317-322, March, 1983. 3 Tab, 18 Ref.

Descriptors: *Oxygen demand, *Mine *Lake sediments, Oxygen, Water pollution Taconite, Sediments, Lake Superior, Dis oxygen.

The possible oxygen demand of tailings de from a mining company into Lake Superi investigated. The disposal site was selected b of the deep, about 274 m, offshore trenc could accommodate the tailings discharge w a significant decrease in depth. The dischar found to exert a small, but definite demand oxygen of the lake sediments. Oxidation of f iron appeared to be the mechanism responsi the observed demand. A model was used t mate the oxygen concentration changes in Superior based on laboratory results. The o losses were estimated to be 0.3 mg/l at the s of the tailings deposit, which would decrea ponentially to 0 mg/l at 5 m above the d One field study indicated dissolved oxyge centration depletions of 0.1 to 0.2 mg/l abo tailings deposit. Other survey results sugge natural variation is greater than predicted o concentration changes from the discharge conite tailings. Taconite tailings have bee charged continuously since 1955, and DO co trations in the bottom waters of Lake Superi exceed 12 mg/l. It can therefore be conclude the discharge of taconite tailings is not hav significant impact on the dissolved oxygen co trations in the lake. (Baker-FRC)

MECHANISMS LEADING TO ENRICHM OF THE ATMOSPHERIC FLUOROCARB CCL3F AND CCL2F2 IN GROUNDWATER.
Arizona Univ., Tucson. Dept. of Hydrolog Water Resources.
A. D. Russell, and G. M. Thompson.
Water Resources Research, Vol 19, No 1, p February, 1983. 4 Fig, 3 Tab, 15 Ref.

Descriptors: *Fluorocarbons, *Ground dating, *Sorption, Fate of pollutants, Air poll Dating, Adsorption, Soil gases, Soil mo Water pollution sources, Industrial wastes.

uorocarbons CCl3F and CCl2F2 were deter-
in distilled water extracts of dry soil samples
sites in Arizona. Soil samples were assumed
tain fluorocarbons in equilibrium with the
here. Mean levels of CCl3F (ng per liter) in
pernatant water were 1.13-6.69; increases
ie control, 0.62, were 83-981%. Mean levels
12F2 (ng per liter) in the supernatant water
).51-1.29; increases over the control, 0.53,
rom -3.7 to 144%. Correlation between the
tage increase in fluorocarbons in the water
and organic matter content was very good
Cl3F and good for CC12F2. The probable
for the increase of fluorocarbons in water is
tion from soil surfaces due to competition
ater molecules for sorption sites. If soil air
tact with recharge water is also in contact
ie atmosphere through cracks and open pore
it may degas, reducing the concentration of
arbons in water reaching the aquifer. Con-
, infiltrating water with little contact with
nosphere would become enriched as it dis-
fluorocarbons from soil air with increased
pressures of these chemicals. These findings
plain some anomalies in groundwater dating
using the fluorocarbon method. (Cassar-

**ER (II) BINDING BY HUMIC ACID EX-
TED FROM SEWAGE SLUDGE: AN
TRON SPIN RESONANCE STUDY,**
e Univ., Lafayette, IN. Dept. of Agronomy.
Boyd, Le. E. Sommers, D. W. Nelson, and
West.
cience Society of America Journal, Vol 47,
p 43-46, 1983. 1 Fig, 2 Tab, 28 Ref.

ptors: *Copper, *Humic acid, *Sludge,
on spin resonance, Soil organic matter, Or-
matter, Chelation, Chemical reactions, Pro-
ate of pollutants.

g of Cu(++) by humic acid extracted from
e sludge was studied with electron spin reso-
spectroscopy. Spectral data of the Cu-humic acid complex and some adducts with nitrogen donors (pyridine, 1,10-phenanthroline, and ethylenediamine) showed that Cu(++) formed two equatorial bonds with humic acid oxygen donor ligands. The data were consistent with the formation of a copper chelate in the original Cu-humic acid complex. The ligand field strength of the humic acid oxygen donor ligands coordinated to Cu(++) was stronger than that of water. Cu(++) also appeared to form axial bonds with humic acid donor ligands originating from proteinaceous materials associated with the sludge humic acid. Characterization of an adduct with glycylglycine showed that the dipeptide formed coordinate bonds with Cu(++) bound to humic acid. (Cassar-FRC)

LONG-TERM IMPACTS OF SURFACE MINING ON GROUND WATER IN TEXAS DELTA PLAIN LIGNITE MINES,
C. R. Pollock.
Bulletin of the Association of Engineering Geologists, Vol 20, No 1, p 1-4, 1983. 2 Fig, 7 Ref.

Descriptors: *Groundwater pollution, *Lignite, *Mining, Texas, Groundwater resources, Water supply development, Aquifers, Water quality, Mine wastes.

Long-term hydrogeologic impacts of surface mining were investigated in 25-year-old mined land at an active delta plain lignite mine in Texas. Four monitoring wells were installed near a runoff collecting lake that occupies part of the initial box cut of the original mine. A groundwater system has developed in this old surface mined land. The water table in the resaturated spoil is at the same depth as in the pre-mine overburden, not more than 6 to 8 m below the surface. Mapping of the potentiometric surface in the mine spoil reveals that ground water in the immediate vicinity of the lake discharges to the lake. However, groundwater distant from the lake generally flows to the south-southeast in the direction of regional groundwater before mining. By studying the water chemistry of resaturated mine spoil at this active delta plain lignite mine it was determined that long-term adverse impacts of surface mining on groundwater hydrology are minimal. Resaturated mine spoil is a water table aquifer that is capable of transmitting as much water as the pre-mine overburden; mine spoil will generally resaturate within 20 years after mining. Interruptions of groundwater flow in surface mined land should be of limited duration. Spoil water quality is similar to but more mineralized than that of the pre-mine overburden water. Surface mining should not seriously degrade groundwater quality beyond the mine boundaries. (Baker-FRC)

TRACE METALS IN A TROPICAL RIVER ENVIRONMENT - SPECIATION AND BIOLOGICAL TRANSFER,
Bhabha Atomic Research Centre, Bombay (India). Health Physics Div.
A. C. Paul, and K. C. Pillai.
Water, Air, and Soil Pollution, Vol 19, No 1, p 75-86, 1983. 1 Fig, 16 Tab, 13 Ref.

Descriptors: *Trace metals, *Speciation, *Rivers, *Sediments, Fish, Rice, Copper, Zinc, Cadmium, Manganese, Industrial outfall, Industrial wastes, Public health.

The transfer and uptake of trace metals such as copper, manganese, zinc, cadmium, nickel, and iron in the river environment were considered. Surface water samples were collected daily from two locations, 100 m apart, at the industrial outfall area in the river. Sediments were sampled from different locations in the river. Samples of milk were analyzed from cows grazing on the contaminated pasture at the industrial zone. Samples of fish were taken from the river. Trace metals were present in varying ratios in the dissolved and suspended fractions in river water. Trace metals, particularly cadmium and zinc showed higher concentration in sediments at the industrial zone, attributed to the industrial pollutions. All metals showed a wide range of concentration in the humic fraction of the sediments. Trace metals were higher in milk from cows fed on contaminated pasture when compared to the control cows. Analyses of fish in the river from different zones indicate varying levels of concentration in tissue. Zinc was generally concentrated in the bone as was manganese. Cadmium showed highest levels in the liver. The total intake of trace metals by a person living in the industrial zone would be calculated on the basis of the average concentration in each food item. Based on the assumption that the person consumes only the items that are produced locally it is estimated that the intake of zinc exceeds that of the reference man by about 3600 micrograms/day. The major intake, nearly 90%, is through rice grown on irrigated fields. The intake of cadmium also exceeds that of reference man, while copper and iron consumption fall short. (Baker-FRC)

THE MOVEMENT OF METALS APPLIED TO SOILS IN SEWAGE EFFLUENT,
Texas A and M Univ., College Station. Dept. of Soil and Crop Sciences.
K. W. Brown, J. C. Thomas, and J. F. Slowey.
Water, Air, and Soil Pollution, Vol 19, No 1, p 43-54, 1983. 5 Fig, 2 Tab, 29 Ref.

Descriptors: *Heavy metals, *Land disposal, *Sewage disposal, Erosion, Permeability, Leaching, Soil types, Water pollution sources, Land management.

The fate of five heavy metals when applied to four diverse soils in secondary treated sewage effluent was examined. Spiking of the samples was done to simulate long term metal additions from effluents low in total metals. The sewage effluent had a mean BOD of 6.4 mg/1, a mean total organic carbon of 34.4 mg/1 and a pH of 7.8. It was spiked with sulfates of Cd, Cu, Ni, and Zn and the nitrate of Pb to concentrations which averaged 0.82, 0.83, 0.75, 0.91, and 0.74 mg/1 of each metal, respectively. The soils used were Bastrop, a udic paleustalf; Lakeland, a typic quartzipsamment; Nacogdoches, a rhodic paleudalf; and Norwood, a typic udifluvent. Subsamples of the leachate water were collected monthly from all lysimeters throughout the study to determine if any of the metals moved from the soil profiles. Results indicated that while the metals did move in the soil, none entered the leachate collected 150 cm below the surface during this study. Thus even highly permeable soils such as the Lakeland were able to retain the metals applied in sewage effluent and decrease the potential for movement in the groundwater. Since the metals did accumulate in the surface soil, good land management techniques will be needed to minimize the movement of metals via soil erosion. (Baker-FRC)

25 YEARS OF FISSION PRODUCT INPUT TO LAKES SUPERIOR AND HURON,
Ministry of State for Science and Technology, Ottawa (Ontario).
B. L. Tracy, and F. A. Prantl.
Water, Air, and Soil Pollution, Vol 19, No 1, p 15-27, 1983. 4 Fig, 5 Tab, 27 Ref.

Descriptors: *Radioactive wastes, *Water pollution effects, *Lakes, Great Lakes, Lake Huron, Lake Superior, Fish, Fallout, Bioaccumulation, Strontium, Cesium, Antimony, Sedimentation, Lake sediments, Sediment-water interfaces.

At the present time, virtually all fission products in the upper Great Lakes are the result of fallout from nuclear weapons testing. The concentrations of the fission products Sr-90, Sb-125, Cs-137, and Ce-144 in the water, sediments and biota of Lakes Superior and Huron were examined. No significan

differences were noted between concentrations from open water and coastal water in Lake Huron, suggesting that releases from the nuclear generating station at Douglas Point did not have a significant influence on fission product concentration. Sr-90 and Sb-125 appear to be removed from lake water primarily by radioactive decay, whereas rapid settling plays a large role for Cs-137. However, from 3 to 30% of this fission product persists in the water for many years after its introduction. Once deposited in the sediments of the upper Great Lakes, fission products remain at or near the sediment-water interface. This could facilitate their re-entry into the water and could provide an explanation of the persistence of Cs-137 in lake water. Great lakes fish contained concentrations of Cs-137 several thousand times higher than in ambient water. A health evaluation of the effects of consuming water and fish from the upper lakes over the past 25 years shows no basis for concern. The 50-yr committed dose equivalents are well within national and international limits. It is cautioned that a large scale release of fission products from a nuclear facility could lead to elevated concentrations in water and fish, and consequently to an increased radiological burden to surrounding populations for many years to come. AN ASSESSMENT OF ACID RAIN ON LEACHING OF ELEMENTS FROM DELAWARE SOILS INTO GROUNDWATER,
Delaware Univ., Newark. Coll. of Agricultural Sciences.
D. L. Sparks, and C. R. Curtis.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-120849, Price codes: A02 in paper copy, A01 in microfiche. Water Resources Center Completion Report (1983). 18 p, 5 Fig, 2 Tab, 12 Ref. OWRT A-053-DEL(1), 14-34-0001-2108.

Descriptors: *Acid rain, *Leaching, *Groundwater pollution, *Ion transport, Soil properties, Cation exchange, Anion exchange, Leachates, Heavy metals, Delaware.

The effects of acid rain on the kinetics of elemental release from three major Delaware soil types were investigated. All three soils contained low clay and organic matter contents which would indicate rather low buffering capacities. The kinetics of elemental release were evaluated by leaching the soils with simulated acid rain at pH levels of 2.5, 3.4, 4.8, and 5.6. Leachates were collected until an apparent equilibrium in elemental release was obtained. In all soils and at all acid rain pH levels, quantities of basic elemental release were in the order Ca K Mg Na. The amount of heavy metals and Si release were very low. As the pH of the acid rain decreased, the total quantity of each released element increased. In all cases, a rapid initial release of each element was followed by slower release rates. The kinetics of Al release were characterized by a similar time trend. The greatest Al release rates occurred at pH 2.5 and from the soil type with the lowest clay and organic matter contents and thus the poorest buffering capacity. The Al that was released at pH 2.5 from the soils would probably be either monomeric or polymeric Al; however, some release could have occurred from the clay structures. Anionic release, including Ca super -, SO sub 4 super =, and NO sub 3 super -, was evaluated and found to be negligible.

ORGANIC CHEMICALS AND DRINKING WATER,
New York State Dept. of Health, Albany.
N. K. Kim, and D. W. Stone.
Report April 1981. 70 p, 8 Fig, 27 Tab, 22 Ref. 12 Append.

Descriptors: *Organic compounds, *Contamination, *Drinking water, *Chemical wastes, *Groundwater pollution, *Water pollution, Herbicides, Hazardous materials, Toxins, Wells.

In 1977 the New York State Department of Environmental Conservation (DEC) conducted an Industrial Chemical Survey to determine types and amounts of organic chemicals used, stored or manufactured by industries in the state. Data indicate that large quantities exist throughout the state. DEC's spill summary for 1978 shows that many accidental discharges of hazardous material and toxic chemicals occur each year. This has been documented by studies of Long Island's groundwater and upstate New York's supply wells. Some examples of the types of toxic or hazardous material spilled are sodium cyanide, acetone, chromic acid, heavy metal sludge, hydrocarbon waste, paint, pesticides, dry cleaning solvents and PCB's. Pesticides and herbicides identified in the State and Federal drinking water regulations (endrin, lindane, methoxychlor, toxaphene, 2,4-D and 2,4,5-TP Silvex) were generally not found in surface source community water systems. The data show that contamination is widespread and not restricted to a particular area of the state. In Nassau and Suffolk County wells, the most common contaminant was tetrachloroethylene. SURVIVAL AND DISTRIBUTION OF AEROMONAS HYDROPHILA IN NEAR-SHORE COASTAL WATERS OF PUERTO RICO RECEIVING RUN DISTILLERY EFFLUENT,
Puerto Rico Univ., Rio Piedras. Dept. of Biology.
E. J. Biamon, and T. C. Hazen.
Water Research, Vol 17, No 3, p 319-326, March, 1983. 8 Fig, 5 Tab, 29 Ref.

Descriptors: *Bacteria, *Organic matter, *Wastewater disposal, Survival, Fate of pollutants, *Aeromonas hydrophila, Coliforms, San Juan, *Puerto Rico, Fermentation, Plumes, Pathogens.

Aeromonas hydrophila densities and water quality parameters were determined at a control station and at 5 stations in the plume of a large rum distillery discharge near San Juan, Puerto Rico. Densities of A. hydrophila varied from 10 CFU per ml at the unpolluted site to 1 million CFU per ml at the point of discharge. Densities of A. hydrophila were significantly higher in the plume than at the control site and decreased with distance from the discharge point. The density of the pathogen showed significant correlation with temperature, total phosphorus, total organic carbon, and orthophosphate. Suspensions of A. hydrophila placed in diffusion chambers at the discharge source survived and increased in density. Those placed in the unpolluted site rapidly decreased in density with time. Densities of fecal coliforms and standard count bacteria within the plume were 0.3 to 50 CFU per ml and about 1 million to 100 million CFU per ml, respectively, and were not correlated with distance from the source. INVESTIGATIONS ON BOTTOM SEDIMENTS OF HUNGARIAN RIVERS AND RESERVOIRS. DETERMINATION OF MINERALOGICAL COMPOSITIONS BY INSTRUMENTAL ANALYTICAL METHODS,
Veszpremi Vegyipari Egyetem (Hungary). Inst. for Analytical Chemistry.
J. Hlavay, J. Kristof, J. Borszeki, F. Laszlo, and P. Literathy.
Water Research, Vol 17, No 3, p 327-332, March, 1983. 5 Fig, 7 Tab, 11 Ref.

Descriptors: *Mineralogy, *Sediments, *Adsorption, Fate of pollutants, Sajo River, Tiszar River, Kiskore Reservoir, *Hungary, Bottom sediments, Clays, Surface area, Reservoirs, Rivers.

Bottom sediments from 10 sites in the Sajo River, Tisza River, and Kiskore Reservoir, Hungary, highly polluted with industrial wastes, were analyzed to determine the mineralogical composition, organic matter content, degree of crystallinity, silicon dioxide content, quartz content, and specific surface area. These investigations, using infrared spectroscopy, thermoanalytical methods, classical analytical methods, X-ray powder diffraction, and vapor absorption measurements, showed that properties of sediments from all the sites and the connected reservoir differed only slightly. This indicates that the sediments studied have simil
ities to adsorb heavy metals and to sett
similar rates. Specific surface areas were 8
m per g, with the higher values obtained f
voir samples. (Cassar-FRC)

Descriptors: *Phenols, *Degradation, *Se Fate of pollutants, *Trichlorophenol, Su sediments, Biodegradation, Microbial degr Organic compounds, *Delaware River.

Water and bottom sediment from 11 site Delaware River from Mile 146 (Wash Crossing) to Mile 63 (New Castle) were studies of 2,4,6-trichlorophenol (TCP) bio tion (initial concentration, 50 microgra liter). Incubation of sterilized control showed no degradation during the 22 days and very little adsorption onto sedimen sampling site had no correlation with deg rate in either water or water/sediment Water systems showed a lag period seve before TCP degradation began; water/s systems did not. Averaged half-lives we ment/water, unstirred, 7.6 days; water alo days. Using different substrates half-live glass beads, 5 days; sterile gravel, 10 days sand, 13 days. The relationship between su sediment and rate of degradation was indic the following half-lives: 7 days for a 1 g suspension. A positive relationship was sh the rate of biodegradation and exposed area. This study showed that surfaces for b attachment play an important role in m degradation. (Cassar-FRC)

DEGRADATION OF SELECTED P LUREA HERBICIDES BY ANAEROBIC SEDIMENT,
Clemson Univ., SC. Dept. of Microbiology
H. H. Attaway, III, M. J. B. Paynter, and N Camper.
Journal of Environmental Science and Heal B, Vol 17, No 6, p 683-699, 1982. 6 Tab,

Descriptors: *Herbicides, Degradation, Sed *Monuron, *Diuron, *Fenuron, *Microbial dation, Anaerobic conditions, Ponds, Fate lutants, Urea pesticides, *Anaerobic digestio

Anaerobic degradation of the herbicides monuron and fenuron in pond sediments wa tigated. Sediment from a diuron-treated po halogenated diuron to 3-(3-chlorophenyl) methylurea in 17-25 days. Sterile sedimen ments from non-diuron-treated ponds, or in faces of clay, sand, or cellulose did not d diuron. Degradation occurred at 25 and 3 not at 37C or at 15C or below. Degradati most rapid at 30C. Diuron-treated sediment under refrigeration for 8 months retained its to degrade diuron. Monuron, 3-(4-chlorop 1,1-dimethylurea, and fenuron, 1,1-dime phenylurea, were not degraded by pond sed The fact that the para-chlorine of monur not removed implies that the enzyme(s) resp for reductive dehalogenation requires electi tivity of the meta-chlorine, as in diuron. VERTICAL MOVEMENT OF GROUND WATER UNDER THE MERRILL FIELD LAND- FILL, ANCHORAGE, ALASKA,
Geological Survey, Anchorage, AK. Water Resources Div.
G. L. Nelson.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver CO 80225, Price: $3.50 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-1016, 1982. 34 p, 8 Fig, 1 Tab, 5 Ref.

Descriptors: *Groundwater, *Hydraulics, Deep percolation, Sanitary fills, Vertical permeability, Aquifer testing, *Alaska, Anchorage.

Shallow groundwater under the Merrill Field sanitary landfill at Anchorage is polluted by leachate. Wells, including three Municipal-supply wells, obtain water from two confined aquifers 100-300 feet beneath the landfill area. Aquifer-test data and information on subsurface geology, ground-water levels, and properties of materials were used to estimate vertical gradients and vertical permeabilities under the landfill. The authors 'best estimates' of vertical permeabilities of two confining units are 1 x 10 super -2 foot per day and 2 x 10 super -4 foot per day. Theoretical travel-time calculations indicate that minor amounts of pollutants may reach the upper confined aquifer after many tens of years, but that water of the composition of the leachate probably would not reach the aquifer for more than three centuries. The range of error in the theoretical travel-time calculations is likely to be plus or minus a factor of two or three. (USGS)

Descriptors: *Asbestos, *Water supply, Bedrock, Drinking water, *Groundwater, Minerals, Quarries, Reservoirs, Rivers, Pollution, X-ray, Electron Microscopy, Rutile, Titanium oxide, Chrysotile, Crocidolite, Tremolite-Actinolite, *New Jersey, Staten Island, New York.

On the basis of the distribution of asbestos in the northern New Jersey area, four principal target areas were investigated for contamination of water supplies by bedrock asbestos: Staten Island, N.Y., Mendham, N.J., Franklin, N.J., and Easton, Pa. In the Silver Lake Reservoir in Staten Island, N.Y., where chrysotile from serpertinite bedrock exposures is a potential source of contamination, chrysotile asbestos levels of 15 to 86 million fibers per liter (MFL) were measured, with an average of 53 MFL. In Mendham, N.J., ground and surface water sources of municipal drinking water range in crocidolite fiber content from 0 to 4.7 MFL and probably originates from a major crocidolite-bearing fault zone that runs through the town. Franklin, N.J. was investigated to determine whether quarry runoff was contaminating a downstream water supply. Significant amounts (1.1 to 2.0 MFL) of tremolite-actinolite asbestos were found in a stream receiving quarry runoff. Asbestos levels of 0.3 to 3.45 MFL were found in the municipal supply, and probably result from a combination of natural bedrock erosion, ambient environmental contamination, and quarry runoff. Tremolite-asbestos from faulted marble was suspected as a contaminant of College Hill Reservoir, in Easton, Pa. However, asbestos levels at this location were not significantly above background.

Descriptors: *Reservoirs, *Water quality, Nitrogen, Phosphorus, Algal growth, Chlorophyll A, Nutrients, Quebec.

Nitrogen and phosphorus dynamics were studied during a 20-month period in two adjacent reservoirs used by the city of Granby, Quebec, Canada, for domestic and industrial water supplies. The two impoundments have a common water supply, the North Yamaska River, but differ considerably in their physical and biological characteristics. The river water entering the two reservoirs was highly enriched in phosphorus, reflecting land use practices in the upstream watershed. Concentrations of dissolved phosphorus at the inlet greatly exceeded the generally accepted water quality standards for standing waters. During summer stagnation, a lagged relationship was observed between indigenous phytoplankton chlorophyll-a and algal growth potential. Fluxes through each reservoir for a variety of parameters, including chlorine, conductivity, inorganic nitrogen, total phosphorus, algal growth potential, and chlorophyll-a, were calculated from data on concentrations and discharge measured at the inlet and outlet of each impoundment. Mass balance analysis showed that the two reservoirs were similar with respect to chlorine, inorganic nitrogen, phosphorus, and chlorophyll-a, but differed significantly with respect to the algal growth potential. The input-output budgets for algal growth potential were balanced in the main-stream reservoir, but were strongly negative in the off-channel reservoir. The implications of the study results for the modeling of water quality in other reservoirs are briefly discussed. (Carroll-FRC)

THE EFFECT OF THERMAL EFFLUENT, BEFORE AND AFTER MACROPHYTE HAR- VESTING, ON STANDING CROP AND SPE- CIES COMPOSITION OF BENTHIC MA- CROINVERTEBRATE COMMUNITIES IN LAKE WABAMUN, ALBERTA,
Calgary Univ. (Alberta). Dept. of Biology.
J. B. Rasmussen.
Canadian Journal of Zoology, Vol 60, No 12, p 3196-3205, 1982. 6 Fig, 4 Tab, 49 Ref.

Descriptors: *Thermal pollution, *Temperature effects, *Benthic environment, Alberta, Lakes, Lake Wabamun, Canada, Heated water, Macroinvertebrates, Oligochaetes.

Prior to macrophyte harvesting the heated area of Lake Wabamun had higher submerged macrophyte production, greater amounts of plant detritus in the sediment, and a higher standing crop of benthic macroinvertebrates than the unheated area. In the heated area the warmest spots supported a community dominated by tubificid oligochaetes, and the moderately heated areas supported com-

munities dominated by large Chironomus, mainly of smaller chironomid species. The heated area was subjected to mechanical macrophyte harvesting, which removed the majority of the submerged macrophytes. This reduced the amount of plant detritus within the sediment and also the standing crop of benthic macroinvertebrates in the heated area. Species composition of the oligochaete-dominated community was not affected by harvesting. Species composition of the Chironomus-dominated area was greatly affected by harvesting and became more similar to that of the unheated area, with densities of the large Chironomous species being reduced to low levels, while the densities of smaller chironomid species increased. These findings suggest that the effects of thermal effluent on benthic animal communities in Lake Wabamun are partly a consequence of increased macrophyte production and the accumulation of detritus. However, the details of this interaction are obscure. (Baker-FRC)

Descriptors: *Trace metals, *Rivers, *Distribution, Zinc, Cadmium, Industrial wastes, Monsoons, Periyar River, Sediments, Water pollution effects, India.

The distribution of trace metals in the Periyar Rive. in Kerala and its backwaters was studied from 1976 to 1980. The river from Kalady to Mcolampalli, a distance of about 50 km, has been divided into 3 zones: background, industrial, and backwater. In view of the overwhelming impact of monsoon runoff in the river flows a seasonal separation of the studies between monsoon and non-monsoon periods has been made. Background concentrations of trace metals increased in the river water during the summer partly due to increased solubilization and partly due to concentration through evaporation. The sediments also reflect the corresponding seasonal changes in the concentrations. There is preferential concentration of the finer particles that remain suspended. Meandering of the stream during monsoon, which results in reduction of flow velocity, is responsible for large scale deposition of suspended solids at the industrial zone. Industrial effluent discharge enhances the concentration of Zn and Cd, both in the water and in the sediments, in the industrial zone. The concentration of Mn and Cd in the water approaches the recommended safe limits for drinking water. Deleterious effects on smaller organisms are reported and possible synergistic effects are cited as the river is the recipient of a wide variety of chemical pollutants. There is also evidence for solubilization of trace metals in the backwater zone under the influence of higher salinity in summer. Solubilization may be regarded as a significant property by which the trace metals get transported to the marine regime. (Baker-FRC)

As part of an effort to understand the relationships between nutrient dynamics and nuisance algal blooms, this study addresses the transfers (among the air, water, sediments, and microorganisms) and transformations (from one form of the nutrient to another) of nitrogen nutrients as they travel through the Neuse River. Two sampling sites were chosen, but there was not as much difference in N kinetics between the upriver and downriver stations as had been anticipated. This probably stemmed from the fact that river flows were relatively high during the study, and the downriver area experienced riverine conditions (high dissolved inorganic nitrogen, low algal productivity), rather than the estuarine conditions (low DIN, high algal productivity) typical of other years. Phytoplankton biomass in the river was closely correlated (inversely) with river discharge rate. About 80% of the DIN assimilate by algae and bacteria in the river was NH sub 4-N, even though NO sub 3-N concentrations were usually 5-10 fold higher than NH sub 4-N. Significant NOsub 4-N utilization can be expected to occur only if the NH sub 4-N becomes depleted. During this study, NH sub 4-N did not become depleted because ammonification rates usually were high enough to provide enough DIN to supply the assimilation needs. Given the rapid recycling of NH sub 4-N and the large reservoirs of NO sub 3-N in the Neuse, DIN inputs will need to be reduced greatly before N limitation can act to control algal production.

OWRT A-058-PA(1), 14-34-0001-2140.

Descriptors: *Acid rain, *Soils, *Acid deposition, *Soil buffer capacity, *Soil acidification, *Computer simulation model, Cation exchange, Sulfate adsorption, Base saturation, Acidity, Mineral degradation, Aluminum hydrolysis, pH, Aluminum toxicity, Cation leaching, Soil sensitivity, Simulation, Prediction equations, Atmospheric sulfur, Atmospheric nitrogen.

Pennsylvania shares with its neighboring states the most acidic deposition that falls in the United States. The effect of acidity in the deposition on soils has not been fully evaluated. A computer simulation model was developed to determine the impact of various inputs of acid deposition on Pennsylvania soils. The model simulates the changes that occur in the solid phase of soils in humid, temperate climates that are undergoing acidification and cation leaching. To obtain predicitons about soil properties which closely matched actual field conditions, the state was divided into 10 regions based on physiography, county borders, and proximity to 1 of the 10 precipitation monitoring stations established by the Pennsylvania Department of Environmental Resources. Information from The Pennsylvania State University Soils Data Base for the major soil associatio each of these 10 regions, and the acco precipitation data, were used as input to t Simulations creating the 'worst case scen designed using data for uncultivated an soils, and without a forest canopy or lit Soils were classified into sensitivity cla on the amount of time required for the so a threshold value of pH less than or eq aluminum concentration in the soil solut mg/l in the upper horizon,or aluminum c tion in the soil solution of 0.1 mg/l in horizon. Very sensitive soils reached a value within 30 years, sensitive soils att value within 60 years, slightly sensi reached it within 90 years; non-sensitive not attain critical levels within 90 years. model, simulation results showed the Pen soils were either very sensitive or non Soils at the threshold values at the beginn simulation were very sensitive, while th the critical levels from the start of the were classified as non-sensitive. Thus, sensitive soils contain sufficient buffer c withstand acid deposition inputs at pre for at least 90 years. Correlation analysi results indicates that base saturation, exc cations, exchangeably acidity, and pH closely associated with the sensitivity of vania soils to acid deposition. Cation capacity and sulfate adsorption showed association with soil sensitivity class pre the model.

nty, Murderkill River Marshes.

partina cynosuroides marsh bordering a tidal
receiving sewage effluent was compared with a
lar marsh on a tidal gut receiving no sewage
ent. S. cynosuroides annual net aerial primary
luctivity ranged from 313-746 gdw m-2 yr-1
was similar for the effluent and control
shes. If all plant species are included in the
ary production calculation, the marsh on the
ent creek averaged 1050 gdw m-2 yr-1 and the
h on the control creek averaged 800 gdw m-2
The decomposition of S. cynosuroides leaves
stems from litter bags suggested that decompo-
n in the effluent marsh was significantly faster
in the control marsh. Analysis of plant tissue
ated plants in the effluent marsh had a signifi-
y higher nitrogen concentration than plants
the control marsh early in the growing
on. Near the end of the growing season, plants
the effluent marsh had lower or similar nitro-
concentrations to the plants from the control
h. Despite very high concentrations of ammo-
n the tidal water flooding the effluent marsh,
y uptake of nitrogen by S. cynosuroides ap-
ntly did not occur. Lower soil salinities result-
from the large input of sewage effluent also
ributed to the observed differences between
ontrol and effluent marshes.

Dissolved oxygen, Oxygen.

gical standards for water quality in the
nes Estuary were established, using 5 catego-
(A to E, good to anoxic respectively), each
ed by the composition of the populations of
atory fish, estuarine fish, and estuarine ma-
croinvertebrates. These were correlated with dissolved oxygen values. During periods of recovery from pollution the rate of recovery is most rapid in fish, followed by mobile invertebrates, and then sedentary invertebrates. For example, a C quality water (poor) with a C estuarine invertebrate community may contain a B fish population, indicating improving water quality, or a D fish population, indicating worsening conditions. The third quarter minimum dissolved oxygen level of the Thames increased from 5.5% in 1968 to 44.2% in 1979. This was reflected by changes in the aquatic community: establishment of the prawn Palaemon longirostris in 1976, invasion of marine invertebrate species, and the increasing presence of smelt and rainbow trout, formerly sighted only on rare occasions. SIGNIFICANCE OF EUTROPHICATION IN WATER SUPPLY RESERVOIRS,
W. W. Walker, Jr.
Journal of the American Water Works Association, Vol 75, No 1, p 38-42, January, 1983. 4 Fig, 35 Ref.

Descriptors: *Eutrophication, *Storage reservoirs, *Phosphorus, *Water quality control, *Watershed management, *Phosphorus removal, *Literature reviews, Model studies, Reviews, Organic loading, Organic carbon, Water pollution effects, Water supply, Limiting nutrients, Costs.

Some key relationships between eutrophication of surface water supplies and the costs and quality of finished water are reviewed. In view of current concerns over organohalides, problems with organics are most significant. Data from lakes and reservoirs in the United States show a positive correlation between total phosphorus and total organic carbon measurements. This correlation is indicative of the role of phosphorus as the limiting nutrient in the growth of aquatic plants and algae. The control of phosphorus export in watersheds is a potentially significant and cost-effective means of dealing with organics-related problems. Regionally-calibrated empirical models may be used with reservoir and watershed monitoring data to assess the extent, significance and controllability of phosphorus-related water quality problems. Water shed assessments also provide a means of arriving at local solutions to organics-related problems and of formulating land-use policies to protect water quality. (Geiger-FRC)

THE SENSITIVITY OF CEDAR SWAMPS TO THE EFFECTS OF NON-POINT SOURCE POLLUTION ASSOCIATED WITH SUBURBANIZATION IN THE NEW JERSEY PINE BARRENS,
Rutgers - The State Univ., New Brunswick, NJ. Center for Coastal and Environmental Studies.
J. G. Ehrenfeld, and J. P. Schneider.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-136779, Price codes: A03 in paper copy, A01 in microfiche. Completion Report, September 1983. 42 p, 31 Fig, 32 Tab, 39 Ref, 8 Append. OWRT A-065-NJ(1), 14-34-0001-2132.

Descriptors: *Nutrients, *Non point pollution sources, *Swamps, Wetlands, *Urbanization, *Water pollution effects, Water level fluctuations, Plant communities, Plant growth, Urban watersheds, Heavy metals, Cedar bogs, Cedar trees.

Nineteen swamps dominated by Chamaecyparis thyoides were chosen to represent the following gradient of increasingly severe impacts due to watershed development: (1) isolated sites, far from roads; (2) isolated sites, near roads; (3) suburban sites with indirect runoff; and (4) suburban sites receiving storm sewer input. In both types of suburban sites, 'typical' Pine Barrens species were lost and many weeds and exotics invaded. Herb, shrub and fern densities did not change significantly along the gradient. The sites receiving storm sewer input showed an increased uptake of phosphorus and lead, but no significant changes for N, Cu or Zn; sites with indirect runoff showed no changes in tissue element concentrations. Sphagnum cover and cedar seedling density decreased sharply with disturbance. Cedar growth rate was found to be a complex function of tree age and site type; there was some evidence of increased increment growth with age in both kinds of suburban sites. In summary, the presence of direct stormwater input to cedar swamps causes marked changes in community structure, vegetation dynamics, and plant tissue element concentration. Developed watersheds, or even roads proximate to swamps, also cause changes, though less drastic, from conditions in swamps in undisturbed areas.

IMPACT OF CHANGING ACIDITY ON THE TROPHIC DYNAMICS OF PINE BARRENS PLANKTON COMMUNITIES,
Rutgers - The State Univ., Camden, NJ. Dept. of Biology.
M. D. Morgan.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-136803, Price codes: A03 in paper copy, A01 in microfiche. U.S. Dept. of the Interior, OWP. Center for Coastal and Environmental Studies Completion Report, Rutgers Univ., New Brunswick, N.J., September 1983. 38 p, 17 Fig, 3 Tab, 27 Ref. OWRT A-066-NJ(1), 14-34-0001-2132.

Descriptors: *Zooplankton, *Acid deposition, Nutrients, Bosmina coregoni, Lakes, Primary productivity, Hydrogen-ion concentration, *New Jersey, *Pine Barrens, Ponds, Oswego Lake, Nescochague Lake.

The physical, chemical, and biological limnology of Oswego Lake (an undisturbed New Jersey Pine Barrens pond), and Nescochague Lake (a pond disturbed by extensive agricultural and residential development) was investigated from June 1981 - May 1983. The impact of disturbance was most evident in pH and nutrients. On all occasions, the pH of Nescochague Lake (mean, based on H super + concentration = 5.3, range 4.5-7.8) exceeded the pH of Oswego Lake (mean - 4.2, range 3.9-4.6). Concentrations of NO sub 3 -N and total P were about 50 times greater in Nescochague Lake than in Oswego Lake (NO sub 3 -N range from 200-800 and 1-25 ug/L, respectively, and total P ranged from 240-600 and 2-16 ug/L, respectively). The biological response to these differences was most evident among the phytoplankton, which exhibited both greater biomass and productivity. Surprisingly, in view of the major differences in pH, the zooplankton communities of these ponds, except for differences in density, were quite similar. Over the two years studied, 35 species were collected from Oswego Lake and 29 from Nescochague Lake. Only 6 species were unique to Oswego Lake and none were unique to Nescochague Lake. In addition, both ponds were dominated by the same species (Bosmina coregoni in the spring and summer, and Eucyclops agilis and Chydorus brevilabris in the fall and winter). Field and laboratory experiments demonstrated that much of the increased pH of Nescochague Lake was a temporary result of high rates of photosynthesis, so that in the winter and at night, the pH approached levels characteristic of Oswego Lake. These periodic reductions in pH apparently restricted the zooplankton to a primarily acid tolerant assemblage, thus, explaining the overall similarity between the communities in Oswego and Nescochague Lakes. Alteration of Nescochague Lake pH in experimental enclosures confirmed this conclusion.

5D. Waste Treatment Processes

WASTEWATER TREATMENT BY SOILS: ROLE OF PARTICLE SIZE DISTRIBUTION,

Indian Inst. of Tech., Kanpur. Dept. of Civil Engineering.
V. Tare, and S. D. Bokil.
Journal of Environmental Quality, Vol 11, No 4, p 596-602, October-December, 1982. 9 Fig, 5 Tab, 18 Ref.

Descriptors: *Wastewater disposal, *Particle size, *Land application, Wastewater treatment, Soil properties, Sand, Silt, Land disposal, Ammonia, Nitrogen removal, Phosphates, Coliforms, Bacteria, Chemical oxygen demand.

Wastewater was treated by percolation through 7.5 cm diameter soil columns containing 100% sand, 100% silt, and mixtures in the proportions 80:20, 60:40, 40:60, and 20:80. Particle size distribution of the soil was a significant factor in effective wastewater treatment. A 60:40 sand:silt mixture was most suitable, combining the faster percolation rates of the sand with the better pollutant assimilation of the silt. A formula was developed for COD removal in soil as a function of depth. For the optimum soil system used in this study the depth below which no significant COD removal occurred was 45 cm. The overall COD reduction rate increased for about 16 days after initiation of wastewater flooding, then decreased, indicating that wastewater application should not be continuous but alternated with dry periods. Although phosphate removal was complete at <15 cm depth in soils containing part silt, 1-2 mg per liter phosphate was found in effluents at the 30 cm depth in sand. Removal of ammonia and total N was dependent on soil particle size, soil sorptive capacity and cation exchange capacity. Coliform concentrations were reduced by 1 order of magnitude in the sand and to zero in the optimum soil system. (Cassar-FRC)

IMPROVEMENT OF WATER USE EFFICIENCY IN IRONWORKS (RATIONALISIERUNG DER WASSERVERWENDUNG IN BETRIEBEN VON EISENHUTTENKOMBINATEN),
Forschungsinstitut fuer Wasserwirtschaft, Prague (Czechoslovakia).
P. Dockal.
Wasserwirtschaft-Wassertechnik, Vol 32, No 8, p 275-276, 1982. 4 Tab, 7 Ref. (No English Summary).

Descriptors: *Industrial water, *Refinery wastes, *Water cooling, *Wastewater treatment, *Pollution, Industrial wastewater, Cooling, Canals, Technology, Temperature, Oil, Suspended solids.

Iron and steel industries are among the largest consumers of water, requiring large quantities for various uses. In the last 10 years, new methods of recycling industrial waters have been developed. Experience has shown that increasing demands for steel quality result in greater wastewater pollution. New wastewater reuse methods are illustrated, based on a mixed-type plant including the Neue Hutte Ostrava. Water economy is visualized in terms of open and closed loops. Well planned recycling has minimized pollution under normal conditions, but breakdowns and work schedule changes can interfere with these plans. Principal efforts in the next few years should probably be directed toward dissipation of waste heat, minimizing the effects of operational interruptions, and improving wastewater treatment in the individual processes. (Titus-FRC)

SKOOKUMCHUCK DECOLORIZATION MEETS HIGH EXPECTATIONS.
Pulp and Paper Journal, Vol 35, No 5, p 12, 14, 1982. 2 Fig

Descriptors: *Wastewater treatment, *Color, *Settling ponds, *Infiltration, Organic compounds, Canada, Industrial wastes, Kootenay River.

The $2.5 million rapid infiltration decolorization system installed in the fall of 1981 for a forestry operation in Canada effectively eliminated 90% of the effluent color which was formerly contaminating the nearby Kootenay River. The process begins with the effluent percolating through the soil, so that the dissolved organic solids were precipitated by soluble ions characteristic of the soil in the Kootenay River valley. These larger size insoluble molecules are then filtered by the soil. During the rest period, decomposition of some of the organic components left in the soil generates carbon dioxide which locally acidifies soil particles, thus releasing more soluble ions for the next dosing cycle. The treatment system also includes a polishing step, where the effluent remains in a 2.5 day basin to remove solids biologically generated in the aeration pond. It is after this polishing step that the rapid infiltration system comes into play. To evaluate effectiveness of the system at Skookumchuck, a total of 31 monitoring wells were drilled for a cumulative depth of about 2,800 feet. These wells have been installed to monitor groundwater hydrology and the effect of effluent on groundwater quality. (Baker-FRC)

EMPLOYING ACUTE AND SUBACUTE TOXICITY MEASUREMENTS IN ON-SITE BIOMONITORING STUDIES,
Weyerhaeuser Co., Tacoma, WA. Environmental Technical Dept.
J. N. Fisher.
Tappi Journal, Vol 65, No 11, p 89-91, November, 1982. 2 Tab, 4 Ref.

Descriptors: *Wastewater treatment, *Effects of pollution, *Pulp and paper industry, Industrial wastes, Fish, Toxicity, Regulations, Secondary wastewater treatment.

On-site monitoring of pulp and paper mill effluents was conducted at various sites in 1978-1980. Since installation of technology designed to comply with the Best Available Technology (BAT) requirement of the EPA designation could be costly, information was specifically sought which might indicate that a waiver could be requested from BAT installation. Pulp and paper effluents from well-operated secondary treatment systems showed little or no acute toxicity to fish. Even though raw effluent toxicity varied widely, secondary treatment systems were 90-95% efficient in removing acute toxicity. Avoidance and leucocrit responses in test fish occurred in the range of 0.4-0.7 times the median lethal concentrations. Finally, mill bioassay profile results compared with effluent instream concentrations suggest no effect on resident fish populations. (Baker-FRC)

THE EFFECTS OF TEMPERATURE, INLET POLLUTANT CONCENTRATION, AND MICROORGANISM CONCENTRATION ON THE RATE OF AEROBIC BIOLOGICAL TREATMENT,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
V. A. Vavilin.
Biotechnology and Bioengineering, Vol 24, No 12, p 2609-2625, December, 1982. 8 Fig, 1 Tab, 27 Ref.

Descriptors: *Wastewater treatment, *Aerobic treatment, *Mathematical models, Biomass, Biological treatment, Errors, Graphical methods, Pollution load, Model studies, Retention, Pulp wastes, Dissolved oxygen, Mathematical studies.

Traditional models used to describe aerobic waste treatment processes contain systematic errors which become manifest in broad variations of parameters such as the retention time of sewage liquid in the reactor, the biomass concentration in the reactor, the influent pollutant concentration, temperature, and dissolved oxygen concentration. A generalized model has been proposed for aerobic biological treatment that makes it possible to eliminate these systematic errors and reduce the deviation of experimental from calculated values for effluent pollutant concentration. The generalized mathematical model takes into account the pollutant concentration in the initial and purified liquid waste and the biomass in the unit volume of the reactor. Use of the proposed model is illustrated for sewage waters from paper production being oxidized in a laboratory rotating disk and graphical methods. (Geiger-FRC)

DISSOLVED OXYGEN IN HYDRO PLA DISCHARGE INCREASED BY AERATION,
A. R. Sheppard, and D. E. Miller.
Power Engineering, Vol 10, p 62-65, 1982. 7 Fig Tab.

Descriptors: *Aeration, *Dissolved oxygen, *O genation, Wastewater treatment, Turbines, Pow plants, Water quality.

At the Alabama Power Company there has be successful use of a variation of a concept call draft tube aeration to increase the dissolv oxygen concentration of hydroelectric turbine d charges. This type of aeration uses the hydrau characteristics of the draft tube to produce an flow by means of natural aspiration. In gene these systems involve the positioning of ports b neath the turbine wheel. A simple piping syste vents these ports to the atmosphere, making use the low pressure area usually found below t wheel to provide suction needed to naturally as rate air into the draft tube. The basic concept the system was modified by installing deflect plates upstream of the vent ports to further redu pressure occurring at this location. These plat cause the water to separate from the draft tu wall, creating a Venturi type low pressure area ju downstream of the plates, increasing the amount air a unit can aspirate, and consequently increasi the amount of oxygen that can be added to t water. The design process involves evaluation water quality conditions to establish DO increa target; evaluation of deflector plate/vent port co figurations to optimally locate the ports and dete mine plate configuration to produce maximum su tion pressure; simulation of the draft tube as a g transfer rate and thus the air flow requirement and conceptual design of a piping arrangement provide for the intake and supply of air to the ve ports. This type of system, when applicable, is b far the most economical means of increasing D levels of turbine discharges when compared other methods which include molecular oxygen mechanical aeration. IN-STREAM REAERATION OFFERS AN A TERNATIVE TO WASTEWATER TREA MENT,
Eder Associates, Locust Valley, NY.
L. J. Eder, and W. J. Cunningham.
Tappi Journal, Vol 65, No 11, p 85-88, Novembe 1982. 1 Fig, 4 Tab, 6 Ref.

Descriptors: *Wastewater treatment, *Dissolve oxygen, *Pulp and paper industry, Industri wastes, Waste disposal, Wisconsin River, River Biochemical oxygen demand, Reaeration, Ae ation, Cost analysis.

Efforts are underway to amend the discharg permit issued to the Rhinelander Paper Compan in Wisconsin to include waste load allocations fo the maintenance of a 5.0 mg/liter dissolved oxyge standard in the Wisconsin River. The company i currently considering methods for complying wit proposed BCT effluent limitations, tentativel scheduled to become effective in July 1984. Flo diversion of some effluents to their secondar treatment system along with other paper mi modifications should enable their treatment sys tems to produce an effluent within BCT limit Capital costs for reducing the mill's effluent dis charge to meet the most stringent waste load allo cation range from $4,300,000 for spray irrigation t $11,000,000 for secondary treatment and pressur filtration of pulp and paper mill effluents. Operat ing and maintenance costs would increase b $300,000 with spray irrigation and by $515,00 with increased secondary treatment. In-strea reaeration appears to be the least costly method fo meeting waste load allocations. The capital cost o $550,000 for a two-site system is significantly les than the advanced-treatment alternatives. Since th cost of purchased oxygen makes up a significan portion of the total annual costs, the operating cos

d probably be less than $100,000/year. In-
m reaeration could be accomplished in an
onmentally acceptable manner and ensure the
tenance of 5.0 mg/liter DO in the Wisconsin
r. (Baker-FRC)

n recycling metal finishing water to recover
ituents, the economic value of the process
ases with the amount of water recycled. Proc-
conomics depend on the concentration of the
on (the regeneration effluent recovered in the
xchange operation). In treating wastewaters
chrome plating, the process involves separat-
the suspended matter, removing organic
r, and decationizing and deanionizing the
water. An alternative method for the treat-
of chromium rinse water is neutralization
sodium hydroxide, followed by removal of
recipitated heavy metal hydroxides and ad-
ion of chromate anions onto a strongly basic
exchanger. By implementing engineering
ges, a significant improvement is obtained
the use of a counter-current fixed bed system
on a very short column. In the regeneration
anide plating wastewater, a three-column
n consisting of a strongly acidic cation ex-
ger followed by a weakly basic anion ex-
ger and a strongly basic anion exchanger has
successful. The regeneration of the anion
nger is performed with caustic soda in a
er-current manner. Theoretically, recycling
e regeneration effluent is practicable only
the cyanide rinse water, which is separated,
ins only the metals present in the original

eds, Suspended solids, Respiration, Activated
e, Biological oxygen demand.

contact stabilization plant at Isleham, which is
f the Water Authority, was modified with a
eration system according to different Ventur-
models to accept a higher organic loading.
a four month trial period, it was noted that a
ved oxygen concentration of over 1 milli-
/liter could be maintained with vigorous
g and aeration. Respiration rate meas-
ents showed that the oxygenation capacity of
rators in a full-scale activated-sludge plant
equal to or better than their previously as-
l performance in clean water. The plant efflu-
ontained an average of 15 milligrams/liter
nded solids and 19 milligrams/liter of biologi-
xygen demand (BOD). BOD removal was
7.6% and nitrification was nearly 50%. The
naceous respiration rate was determined as an
ge of 1.36 kilograms oxygen utilized per kilo-
gram BOD applied. High sludge-growth rates were observed on the order of 0.92 kilograms of sludge produced per kilogram of BOD applied due to organic load and the use of macerated whole sewage. (Geiger-FRC)

TECHNOLOGY FOR THE REMOVAL OF SYNTHETIC ORGANIC COMPOUNDS,
Ontario Ministry of the Environment, Toronto.
N. W. Schmidtke, and S. A. Black.
Effluent and Water Treatment Journal, Vol 23, No 2, p 47-50, 52-54, February, 1983. 7 Fig, 14 Tab.

Descriptors: *Wastewater treatment, *Organic compounds, *Activated carbon, *Separation techniques, Water treatment, Drinking water, Water pollution sources, Waste disposal, Advanced wastewater treatment, Tertiary wastewater treatment.

The problems caused by synthetic organic compounds (SOCs) in water supplies are numerous and are still being assessed. Research is being done to improve the analytical sensitivity required to detect SOCs in water, wastewater and sludges. Nevertheless, the application of any one single technology will not be the answer to any one SOC problem. However, activated carbon treatment will most likely play an important part in the control of SOCs. Technology for the control of SOCs in drinking water supplies is focusing on the enhancement of existing processes and reuse and reformulation options. The application of stringent in-plant process controls along with careful waste disposal selection is the most cost-effective means of ensuring that only minimum quantities of SOCs will escape in process effluents, enter the environment and require further treatment. EVALUATION OF BIOMASS AGE IN ACTIVATED SLUDGE PROCESSES,
Rome Univ. (Italy). Cattedra di Principi di Ingegneria Chimica.
M. C. Annesini.
Water, Air, and Soil Pollution, Vol 19, No 1, p 55-61, 1983. 4 Fig, 7 Ref.

Descriptors: *Activated sludge process, *Aging, *Biomass, Wastewater treatment, Sludge, Sludge conditioning, Mathematical equations.

A general formulation is presented for expressing biomass age that may be used regardless of aeration tank set up. In this criterion the biological reaction may be likened to completely mixed reactors operated in series. Expressions for a single-unit reactor have been deduced from the general expression, and these are shown to be equivalent to those reported in the art, and for plug flow reactor. An examination of multi-stage processes without recycle shows that whenever the overall effect of phenomena connected to biomass growth is negative biomass age can be deduced from the volumetric residence times of the single reactors. TREATMENT OF BLUE CRAB PROCESSING PLANT WASTEWATER USING PHYSICAL, CHEMICAL AND BIOLOGICAL PROCESSES,
Maryland Univ., College Park. Dept. of Agricultural Engineering.
E. L. Geiger, F. W. Wheaton, and R. B. Brinsfield.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-120856, Price codes: A08 in paper copy, A01 in microfiche. Water Resources Research Center Technical Report No 71, August 1983. 142 p, 27 Fig, 17 Tab, 71 Ref, 2 Append. OWRT A-056-MD(1), 14-34-0001-2122.

Descriptors: *Wastewater treatment, *Wastewater analysis, *Effluents, *Processing plants, Chemical coagulation, Foam fractionation, Ultraviolet radiation, Biological wastewater treatment, Sand filters, Activated carbon, Adsorption.

A treatment system for wastewater from a blue crab processing plant consisting of a biological reactor, sand filter and an activated carbon column was evaluated. Various retention times and dilutions of retort effluent were used to assess reduction of dissolved organics and solids following biological treatment. The necessity of utilizing activated carbon adsorption in conjunction with sand filtration to produce an effluent suitable for UV disinfection was evaluated. These tests indicated: (1) 24-hour batch biological treatment of 5% retort effluent resulted in a mean reduction of 88% in biochemical oxygen demand (BOD sub 5), 86% in chemical oxygen demand (COD), and 29% in total suspended solids (TSS) and produced an effluent with a mean UV transmission of 30%; (2) hourly addition of 5% retort effluent to the reactor during the first 8 hours resulted in reduction of 92% in BOD sub 5 and 90% in COD, 23% in TSS and produced an effluent with a UV transmission of 35% after a 24-hour reaction time; (3) biological treatment using intermittent addition of 1% dilution of retort effluent resulted in organic reduction of 99% in BOD sub 5, 92% in COD, 9% in TSS, and produced an effluent with a UV transmission of 72%. The organics and solids concentrations in the 1% intermittent addition system were reduced sufficiently to allow UV treatment without the use of activated carbon adsorption.

DETERMINATION OF ALGAL-BACTERIAL INTERACTIONS IN WASTEWATER TREATMENT LAGOONS,
Northern Arizona Univ., Flagstaff. Dept. of Biology.
H. Speidel, F. Colwell, and D. Blinn.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-120898. Price codes: A05 in paper copy, A01 in microfiche. Water Resources Research Center Completion Report, Tucson, Ariz. September 1983. 66 p, 13 Fig, 16 Tab, 65 Ref. OWRT A-113-ARIZ(1), 14-34-0001-2103.

Descriptors: Microbial ecology, *Algal-bacterial interactions, Lagoons, *Wastewater treatment, *Oxidation ponds, Chlorella vulgaris, Escherichia coli, Bacterial survival.

The primary objective of this study was to determine whether algae present in wastewater oxidation ponds either enhance or inhibit the survival of pathogenic or indicator bacteria commonly found in wastewater. Population dynamics were studied for pond isolated axenic algae and bacteria in culture together and alone to note whether interactions may be obvious in terms of cell division or survival. Algal-free filtrates from algal cultures were inoculated with bacteria to assess the need for direct contact of interacting organisms. A variety of bacteria and algae were also grown on double-sided plates to allow diffusion of possible extracellular products. In situ studies involved the suspension of bacteria within dialysis bags followed by placement of bags in wastewater lagoons or separation of bacteria from pond water by cellulose acetate membranes in parabiotic tubes. When cultured in the presence of Chlorella vulgaris, Escherichia coli exhibited an increased rate of dieoff relative to the control or when cultivated with Scenedesmus longus. Growth of unialgal, nonaxenic Scenedesmus sp. on double-sided plates was enhanced when cultivated opposite a Pseudomonas sp. Growth of this same alga was inhibited when other bacteria were established. Results of the cocultures of Chlorella vulgaris-Escherichia coli and double-sided plates suggest that the interactions of selected algae and bacteria occur although these are controlled situations and difficult to compare to the complex conditions of a eutrophic pond. Additionally, the double-sided agar plate offers a new method for rapid screening of potential microbial interactions.

RESURRECTION OF DEIGHTON SEWAGE TREATMENT WORKS,
Yorkshire Water Authority (England). Western Div.
C. N. L. Cree.
Water Pollution Control, Vol 82, No 1, p 87-101, 1983. 8 Fig, 2 Ref.

Descriptors: *Sludge disposal, *Rehabilitation, *Industrial wastewater, Wastewater treatment, Deighton Sewage Plant, Huddersfield, *United Kingdom, Sludge digestion, History, Maintenance, Wool wastes.

The Deighton Sewage Treatment Works downstream of Huddersfield on the River Colne, United Kingdom, started with primary sedimentation and sand filtration in 1876. After a series of alterations and additions to accommodate the wastes from the many woolen factories nearby, the sludge treatment facility was declared unrepairable in 1972. The water authority reorganization in 1974 opened the way for improvement of the many deficiencies in the plant: a permanently open inlet control penstock, clogging of the entire system with septic sludge, lack of grit removal, an overflowing sludge tip, constant overflows of untreated sewage into the river, and toxic chemical wastes from industrial dischargers. Some of the problems were solved by improving plant maintenance, replacement of the inoperative penstock, disposal of the humus sludge at sea, removal of excess chemical sludge to a spare bioaeration plant, installation of two sets of vertical bar screens, continuous shift work in the sludge dewatering facility, updating of filter presses, reprofiling the sludge tip, and control of toxic wastewater in influent. WHAT MAKES A SLUDGE COLLECTOR DRIVE TICK.,
Envirex, Inc., Waukesha, WI.
E. P. Saffran.
Water/Engineering and Management, Vol 130, No 1, p 24-25, 28, 45, 1983. 1 Tab.

Descriptors: *Sludge, Mechanical equipment, Wastewater treatment, *Wastewater treatment facilities, Drive, Gears.

The most widely used circular collectors are scraper-type clarifiers and thickeners, suction-type sludge removal units, and process combination collectors. In the scraper-type units, scraping blades are attached to a rotating truss. The blades convey the sludge radially to the center of the collector, where it is removed either by a sludge pump or by hydrostatic pressure. The gravity thickener is a scraper-type collector which allows the sludge to settle and thicken. The circular collector becomes an efficient secondary clarifier when its sludge-removal mechanism is modified. A circular collector has either a peripheral drive or a center drive. There are two types of center drives; the full bridge and the half bridge. The gearhead is the heart of the system. In practical, operational terms an underdesigned bearing may cost less than $10 to replace. The job of installing a new one may take less than 3 hr. However, a complete replacement gear will cost several thousand dollars and will take several days to replace. The various parts and elements of the gearhead must be compatible. The design life of the drive, the gears, the bearings and the rotating structure must all be balanced to achieve the specified performance over the specified lifespan. The proper balance can reduce capital investment and operating costs. It can help ensure the high dependability that is needed in systems which treat municipal and industrial wastewater. (Baker-FRC)

INFLOW DISTRIBUTION IN WASTEWATER COLLECTION SYSTEMS,
RJN Environmental Associates, Inc., Wheaton, IL.
A. J. Hollenbeck, and R. J. Nogal.
Water/Engineering and Management, Vol 130, No 1, p 30-33, 1983. 2 Fig, 7 Tab, 4 Ref.

Descriptors: *Wastewater collection, *Flow characteristics, *Sewer systems, Infiltration, Inflow, Monitoring, Measuring instruments.

Analysis of actual field-verified inflow data for several sewer system evaluation surveys points to certain conclusions regarding the inflow component of infiltration and inflow (I/I) sources in sanitary sewer systems. Inflow appears in general not to be highly concentrated in small parts of a collection system, but rather evenly distributed. It is independent of the flow monitoring interval used to isolate inflow sources. Elimination of large parts of a sanitary sewer system from field survey activities could result in not identifying up to 50% of the largest inflow sources. Inflow reduction is proportional to the extent of the field survey work performed. Rehabilitation by priority can be part of an annual operation and maintenance program. The identification and reduction of excessive flow in a sewer system is complex and is just beginning to be understood by the technical community. It would be inappropriate to abandon the program or search for shortcuts that will not accomplish the stated goals and desired objectives of the I/I reduction and rehabilitation efforts. (Baker-FRC)

TRAINING MAKES ENFORCEMENT EASIER,
Minnesota Pollution Control Agency, Roseville.
G. A. Erickson, and M. W. Herman.
Water/Engineering and Management, Vol 129, No 12, p 24-26, 1982. 4 Tab.

Descriptors: *Wastewater treatment, *Training, *Management, Decision making, Education, Regulations, Enforcement.

The Minnesota Pollution Control Agency was established in 1967 and given authority to administer and enforce all laws relating to water, air and land pollution within the state. Enforcement was used as the main tool in achieving compliance with prescribed standards. To aid in personnel training the agency implemented an operator assistance program in 1976. Its principal objective was to train operators in process control. This would improve their skills and enhance their ability to produce consistently high quality effluent. Selection of a plant for an assistance project basically involves two situations. The facility may be having operational problems causing it to be in noncompliance, or it may currently be in compliance but is approaching the point of being in violation because of difficulties. Since the onset of the program 30 major projects have been completed. Of those 30, four were not successful. Two of these were because of uncooperative operating or municipal officials, while the other two were because the facility would not show any significant improvement in effluent quality. Two thirds of the completed projects involved activated sludge plants in which the major problem was lack of a process control program or interpretation of one already in existence. The remaining third of the projects were carried out at trickling filter plants and controlled discharge stabilization ponds. The time for project completion varied from a minimum of five months to a maximum of 30 months, with an average time of 14 months per project. (Baker-FRC)

ESTIMATING WASTE ACTIVATED SLUDGE,
Clemson Univ., SC.
L. G. Rich.
Water/Engineering and Management, Vol 129, No 12, p 35, 1982. 1 Tab.

Descriptors: *Estimating equations, *Activ sludge process, *Wastewater treatment, Mathe ical equations, Suspended solids, Estimating, F rates.

The estimating of waste activated sludge quant has long been neglected in the wastewater t ment field. Two quantities are of basic importa the daily production rates of total solids an biodegradable solids. Equations are derived situations in which no pretreatment is given to wastewater. In cases where pretreatment is fered, the characteristics of the pretre wastewater are used in place of those of the fluent wastewater. The concentration of solids remaining in the wastewater after 30 aeration at room temperature can be determine a batch mode using an Imhoff cone fitted aeration tubing. In making the determination important to replace the water that evapor from the system on a daily basis. Aeration sh be conducted in the dark to suppress algal gro The volumetric flow rate at which waste activ sludge is processed through a sludge treatm train is also of considerable importance in de The concentration of solids in waste activ sludge withdrawn from the underflow of the ondary clarifier will normally vary between 7 and 10,000 mg/liter. SOLUTION TO ODOR PROBLEM GIVES EXPECTED SAVINGS,
Saratoga County Sewer District No. 1, Mecha ville, NY.
D. J. Rudolph.
Water/Engineering and Management, Vol 129, 12, p 28-29, 1982.

Descriptors: *Wastewater treatment, *Odor trol, *Permanganate, Hydrogen sulfide, Sulf acid, Corrosion, Odors, Sewer systems, Cost an sis, Sludge dewatering.

The Saratoga county wastewater treatment p was seeking a solution to an odor problem. Du a study of the system district personnel discov that the chemical, potassium permanganate, only took care of the odor nuisance but also duced unexpected cost savings in the sludge de tering department. The odor problem had most prevalent at three pumping stations range in load from about 500,000 gpd dow about 60,000 gpd. Hydrogen sulfide concentrat in the atmosphere during the summer were gre than 100 ppm and varied down to 50-60 ppm times of light usage. Not only was the od problem, but the oxidation of hydrogen sulfid the atmosphere to sulfuric acid caused corrosio mild steel equipment and copper contacts of e trical systems. The permanganate is now adde the three pumping stations using dry fee equipped with slurry modules. The resul KMnO4 solution is metered into the wet w directly to the influent sewage. Average dosag about 20-25 lb/mil gal, and total consumption the collection system amounts to about 125 lb/ The permanganate reacts very quickly with hy gen sulfide, and very little gas is now release the atmosphere from the cascading sewage. T processing savings are truly significant. It use cost $209 to process a dry ton of cake. Today cost is $65. (Baker-FRC)

Descriptors: *Aeration, *Oxygenation, *Performance evaluation, *Wastewater treatment, Bubbles, Error analysis, *France.

Aerator tests at sewage treatment plants in France revealed that oxygenation capacities predicted by the manufacturers were close to observed values. In a well mixed tank, using the correct procedure, the relative error in measuring specific oxygen input was 5%. Under less favorable operating conditions, the error was 10%. Average specific oxygen inputs in clean water using different aeration systems ranged from 0.6 to 2.5 kg 02 per kWh. Highest values were obtained with fine bubbles and mechanical agitation. Relationships between oxygenation capacity and specific power consumption are plotted. (Cassar-FRC)

THE CULTIVATION OF ALGAE USING WASTE WATER FROM FEEDLOTS,
Orange Free State Univ., Bloemfontein (South Africa). Dept. of Botany.
A. J. H. Pieterse, J. LeRoux, and D. F. Toerien.
Water SA, Vol 8, No 4, p 202-207, 1982. 7 Fig, 5 Tab, 41 Ref.

Descriptors: *Animal wastes, *Algal growth, *Waste disposal, Aquaculture, Algae, Water pollution control, Water pollution sources, Wastewater treatment, Ponding, Fecal contamination, Bacteria, Cattle feedlots, *Feedlot runoff.

The cultivation of algae in ponded wastewater from a cattle feedlot is described. Treatment is aimed at organic and inorganic wastes produced by animals such as cattle which, for economic and other reasons, are kept in confinement units. Massive amounts of waste material consisting of urine and feces are produced in a concentrated point-source form in these confinement units. Waste materials are usually removed by wash or flush water, representing a major source of environmental pollution with significant health and aesthetic consequences. The largest cattle feedlot system in South Africa contains approximately 30,000 animals, producing waste equivalent to that of a city of 180,000 to 300,000 people. As a matter of urgency consideration must be given in South Africa to the development and application of integrated livestock waste treatment production systems to reduce this pollution. In this study an annual average algal production rate of 10 g/sq m/day of dried algal material was achieved, while a reduction in inorganic nitrogen and phosphorus concentrations in excess of 90% was maintained in a high rate algal pond supplied with feedlot effluent. These results indicate that the algal pond concept can be used efficiently under South African conditions; further study is needed to optimize such a treatment/production system. (Baker-FRC)

THE DESIGN AND CONSTRUCTION OF SPRINGFIELD SEWAGE-TREATMENT WORKS,
Fife Regional Council (Scotland).
J. G. Moore.
Water Pollution Control, Vol 82, No 1, p 37-41, 1983. 1 Fig, 2 Tab.

Descriptors: *Animal wastes, *Municipal wastewater, *Sludge disposal, Wastewater treatment, Springfield, *Scotland, Dewatering, Farm wastes, Filters, Sludge digestion, Land application.

A sewage treatment works was built for the Springfield, Scotland, region, population 7000, which included several sources of problem wastes: a hospital, a college farm, a piggery, an abattoir, and an oatmeal factory. The system contained primary settlement and storm tanks, percolating filters, humus tanks, and sludge holding tanks. A filter belt press was chosen for sludge dewatering. Most disposal of sludge is on farmland; some sludge is being mixed with fly ash for landscaping fly ash lagoons. The new treatment system replaced an overloaded and poorly serviced settlement tank and direct discharge of the industrial effluents to the River Eden. (Cassar-FRC)

AN OVERVIEW OF DIGESTION PROCESSES,
Pretoria Univ. (South Africa). Dept. of Chemical Engineering.
W. A. Pretorius.
Water Science and Technology, Vol 15, No 1, p 1-6, 1983. 3 Fig, 13 Ref.

Descriptors: *Digestion, *Methane bacteria, *Anaerobic digestion, *Wastewater treatment, Sludge digestion, Fermentation, Bacteria, Acetic acid, Fatty acids.

Anaerobic digestion of concentrated wastes relies on the highly specialized methane bacteria to convert organic matter to methane. The process has some disadvantages: the complexity of the bacterial mechanisms and resulting difficulty in process control, low growth rate of bacteria at ambient temperatures, and the necessity for further treatment of effluent before discharge. Methane bacteria include representatives of nearly all basic forms of bacteria. They have in common the ability to oxidize molecular hydrogen to methane in the absence of oxygen. About 70% of the methane formed proceeds through an acetic acid intermediate step. It is possible that methanogenesis proceeds through a dual- or multi-step mechanism involving several types of bacteria and chemical reactions, such as hydrolysis, fermentation, acetate decarboxylation, and methanogenesis. Basic designs of anaerobic digestors include conventional (for sewage sludges and animal wastes), contact process (dilute and soluble biodegradable wastes from such places as meat packing plants), filters (for acetic acid-containing wastewaters), and upflow sludge blanket reactor (for dilute starchy washwaters). (Cassar-FRC)

ENERGY OPTIMIZATION IN SEWAGE AND SLUDGE TREATMENT,
Ruhrverband, Essen (Germany, F.R.).
K. R. Imhoff.
Water Science and Technology, Vol 15, No 1, p 103-114, 1983. 11 Fig, 4 Tab, 2 Ref.

Descriptors: *Sludge digestion, *Energy, *Activated sludge process, *Wastewater treatment, Incineration, Sludge disposal, Costs, Digestion.

The energy requirements of three wastewater treatment systems in Germany are described. Present BOD-population equivalents and energy demands are as follows: Bochum-Olbachtal, 150,000 and 14.4 million kWh per year; Hagen, 270,000 and 6.1 million kWh per year; and Duisburg (proposed plant), 510,000 and 4 million kWh per year. Bochum consists of a conventional activated sludge plant, polishing lagoons, dewatering and incineration of primary sludge, and digestion and incineration of waste activated sludge. Incineration requires 65.5% of the energy used at the plant. The Hagen system is comprised of primary sedimentation, activated sludge, sludge dewatering, and sludge dumping at a 45% solids content. About 75% of the energy used at Hagen is consumed in the activated sludge process and the trickling filters. The proposed Duisburg-Kasserfeld plant will use diffused air activated sludge treatment with sludge thickening, dewatering, and dumping. Diffused aeration will require 51% and other biological treatment 18% of the energy. (Cassar-FRC)
W84-00553

EFFLUENT TREATMENT AND PROTEIN RECOVERY IN EAST ANGLIA.
Water Services, Vol 86, No 1041, p 536-7, 1982. 2 Fig.

Descriptors: *Wastewater treatment, *Food processing wastes, *Wastewater treatment facilities, *Poultry, East Anglia, Protein recovery, Industrial wastes.

Primary considerations in designing a suitable plant for handling an effluent with a COD of almost 4000 mg/liter and a suspended solids content of 1200 mg/liter, apart from meeting the effluent standards, were the availability of space and the minimization of sludge for off-site disposal. Wastewater is collected in an underground sump and pumped by submersible pumps to a screen mounted above a circular balance tank. Wastewater is then pumped to a circular dissolved air flotation tank constructed in glass reinforced plastic; in line to the flotation tank a specific protein precipitant, lignosulfonate, is added. The pH is reduced to 3 by the addition of sulfuric acid. A fraction of the wastewater is diverted from the pipeline to the flotation tank, and part is saturated with air at five atmospheres pressure. The air dispersion water rejoins the main flow at the inlet to the flotation tank, where microscopic air bubbles are precipitated. These adhere to thee protein/fat flocs and carry them to the surface of the flotation tank, where they are removed by a rotating suction arm. The flotated sludge has a total solids concentration of about 10%. The plant occupies a total area of about 300 sq m and can be operated by one person on a part time basis. (Baker-FRC)

CONTROL AND AUTOMATION SYSTEM FOR WITNEY SEWAGE TREATMENT WORKS,
B. E. Marsh.
Water Services, Vol 86, No 1042, p 586-588, 1982. 2 Fig.

Descriptors: *Wastewater treatment facilities, *Automation, *Data acquisition, Instrumentation, Witney Sewage Treatment Works, Thames Water Authority, Computers, *England.

The Wesdac Supervisory Control and Data Acquisition system to be supplied to meet the specified requirements of the Thames Water, consisting of a conventional Wesdac 6 control center and 10 advanced technology outstations, is described. The total modernization of the Western Division of the Thames Water Authority was undertaken with the objective of increasing its throughput from 3700 to 7800 cubic meters/day. Although it was built on the site of an existing sewage treatment works, only the primary sedimentation tanks were retained in changing the process from filter beds to activated sludge. The final phase of the scheme will be installation of instrumentation, control and automation systems providing the following functions: process controllers dedicated to specific items of plant in each of the primary and secondary treatment areas; a central computer coordinating all local controller and centralizing all plant process measurements; visual display terminals distributing the relevant level of process information to operational and management staff; and the facility as a whole acting as a proving ground for computer based systems for the management of sewage treatment processes and providing instrumentation evaluation facilities in conjunction with the Water Research Center. The flexibility of the intelligent outstations enables a wide range of system functions to be implemented: interfacing to new or existing instrumentation, scanning analog and digital data from the plant into a data base held in the outstation, generating local control output commands for the area of plant under its control, and controlling the flow balancing and aeration areas. It is possible to expand the outstation database to include the facility to hold derived analog and digital data. (Baker-FRC)

ADVANCES IN THE TREATMENT OF LIQUID-BORNE SOLID WASTE.
Water Services, Vol 87, No 1043, p 25-26, January, 1983.

Descriptors: *Solid wastes, *Shredders, Waste treatment, *Wastewater treatment, Mono Muncher, Equipment.

The Mono Muncher is effective in macerating solid debris entering sewage treatment plants. This low-speed disintegrator consists of two parallel, contra-rotating shafts with opposed intermeshing teeth set on cutter discs. The shredding action efficiently reduces nylon, timber, plastic, rags, and metal cans. An exceptionally large object will cause the cutters to reverse in an effort to clear the blockage. If this fails, the system shuts down automatically. Energy consumption per cu m of sludge is 0.01-0.02 kW compared with 0.2-0.44 kW for conventional macerators. The Muncher is especially useful in small plants, for which screens are impractical. Pipeline, channel, and submersible models are available. (Cassar-FRC)

DISCUSSION OF: ROLE OF ADSORPTION IN BIOLOGICAL EXTENDED ACTIVATED CARBON COLUMNS, AND AUTHOR'S RESPONSE,
Illinois Univ. at Urbana-Champaign. Dept. of Civil Engineering.
B. E. Rittman, S. J. Randtke, J. D. Lowry, and C. E. Burkhead.
Journal of the Water Pollution Control Federation, Vol 53, No 4, p 512-514, April, 1981. 2 Tab, 7 Ref.

Descriptors: Secondary wastewater treatment, *Activated carbon, *Water treatment, *Wastewater treatment, Adsorption, Potable water.

Comments are presented on the above titled paper by J. D. Lowry and C. C. Burkhead, published in Journal of the Water Pollution Control Federation, Vol. 52, p 389, 1980. Although the discussors agree that adsorption of organics on activated carbon does not enhance biological activity when substrate concentrations are high and oxygen is limiting, they state that the paper does not prove that the opposite case (low substrate concentrations or oxygen not limiting) is true. Therefore, the conclusions cannot be extrapolated to the activated carbon treatment of well-treated secondary effluent or potable water supplies. The author responds that a closer review of his work would indicate that the work is intended only for application to the secondary level of treatment. He cites a reference which concludes that the higher bacterial colony counts on activated carbon are not due to adsorption of organic compounds but to the larger surface area per unit volume of media as compared with nonactivated carbon or sand. iving filter' program begun in 1963 at Penn- ia State University is one of the earliest entatives of land application systems. The m is currently being converted from a small, mental scale to a full scale. The success of ing filter system has been due partly to the al relationship of the system to the commu- serves, the region where it is located, and tural environment in which it operates. The ltural valley of the area is underlain with one and dolomite placed with geologic faults and forested sandstone mountains. In nter of the valley is a low ridge underlain by sandy dolomites. The valley is drained by groundwater flow than by surface s. The proper location for the land applica- te was determined to be on this low ridge in nter of the valley. Here the deep, sandy al soils were very permeable and had a hum- topography. The treated effluent is forced pressure pipe leading from the treatment four miles up to an elevation of about 200 the fields and forests that had been selected land application site. The effluent is distrib- nder pressure by means of a system of main ateral pipes and control valves to evenly l spray heads. The living filter program has led an improved environment for growing crops. Land moisture has been increased and of forage and timber products have helped uce the net costs of sewage disposal. In the of increased buildup of heavy metals, the sed amount of fast-growing irrigated plants ed cadmium from the soil at very rapid There appeared to be no problem with other accumulating either. ISLAND DEWATERING 100% TMP GE, BURNING IN BOILER,
e (J.E.) Co., Research Triangle Park, NC. Hewitt, and R. Ellis.
Pulp and Paper, Vol 57, No 3, p 96-99, March, 1983. 4 Tab.

Descriptors: *Pulp and paper industry, *Sludge thickening, *Dewatering, Incineration, Bear Island Paper Company, Doswell, Virginia, Sludge conditioning, Economic aspects, Vacuum filters, Filters, Centrifugation, Polymers, Hydrasieve, Sludge drying.

The 100% thermomechanical pulp sludge at the Bear Island Paper Company, Doswell, Virginia, is treated with a Hydrasieve and belt filter presses before being mixed with bark and incinerated. This difficult-to-dewater sludge (1.5-2.0% solids) is high in fines content, of which 75-85% passes through a No. 200 sieve. Of the thickening processes tested during development of the sludge treatment program, centrifuge and rotary screen thickener were acceptable, but dissolved air flotation was not. Although centrifuges, diaphragm presses, and V- presses were also effective for dewatering sludge, they were not as economical as the belt filter presses. Operating experience since July 1981 showed that settling and underflow conditions were improved by maintaining a pH of 9.0-9.5 in the primary clarifier feed, adding residual polymer from the press effluent, and slowing down the clarifier rake speed by 60%. Polymer dosage varies with the sludge consistency from 10 to 20 pounds per ton of dewatered sludge. The Hydrasieve produces a 25-33% filter cake which is further dewatered by the belt filter presses. However, the overall cake dryness is limited by serious clogging on the belts. Additional dewatering equipment will be required to produce a filter cake of 35-45%, capable of direct firing of the boiler without added bark. (Cassar-FRC)

SECOND MEMORANDUM OF EVIDENCE TO THE ROYAL COMMISSION ON ENVIRONMENTAL POLLUTION.
Water Pollution Control, Vol 82, No 1, p 123-125, 1983.

Descriptors: *Water quality standards, *Ocean dumping, *Sludge disposal, Acid rain, Estuaries, Monitoring, Fate of pollutants, *United Kingdom.

On invitation from the Royal Commission on Environmental Pollution, evidence on water quality subjects was gathered. Remedial measures for acid rain must be designed to avoid local pollution of water, for example, proper disposal of spent stack gas scrubbing substances. Although international opinion on disposal of sewage sludge at sea has become more negative, the Institute favors a controlled and well-monitored ocean dumping program. Full implementation of the Control of Pollution Act of 1974 will be a problem for estuaries for which little historical data is available to derive mathematical models of mixing and dispersion. Water Science and Technology, Vol 15, No 1, p 49-58, 1983. 6 Fig, 3 Tab.

Descriptors: *Sludge conditioning, *Sludge digestion, *Dewatering, Polymers, Polyelectrolytes, Energy, Centrifugation, Anaerobic digestion, Digestion, Incineration.

In France the current objectives in sludge treatment are to minimize chemical and energy costs, facilitate maintenance of the plant, and promote sludge utilization. Replacement of inorganic conditioners such as ferric chloride and lime with polymers has increased filtration rates and simplified maintenance by eliminating lime storage facilities, lime scaling of equipment, and corrosion from ferric chloride. Separate thickening for primary sludges and biologically treated sludges results in sludges of 5-8% solids content vs. the 3-4% seen in some plants. Experiments showed that thermal digestion, incineration of centrifuged sludge, and digestion of the liquors was not only self-supporting with respect to energy but produced a considerable surplus of heat and gas. SOUTH AFRICAN PRACTICE IN LAND DISPOSAL OF SLUDGE, INCLUDING LEGISLATION AND HEALTH ASPECTS--AN OVERVIEW,
Department of Health and Welfare, Pretoria (South Africa).
G. Oberholster.
Water Science and Technology, Vol 15, No 1, p 151-155, 1983. 5 Ref.

Descriptors: *Land disposal, *Agriculture, *Sludge disposal, *South Africa, Soil amendments, Water pollution prevention, Legislation, Pathogens, Fate of pollutants, Legal aspects, Regulations, Sludge utilization.

In South Africa sewage and sludge disposal practices vary widely throughout the country. Cities have sophisticated treatment systems or dispose of raw sewage in the sea. Rural areas use pit latrines and other simple systems. Data on sludge production is available only for Cape Province. Here 205 tons of sludge per day are produced, 76.4% from biological filters and activated sludge plants. Of the total sludge production, 64.6% is disposed on land, 89% of this for agriculture. Growers are not enthusiastic about land disposal except in sandy soils which benefit from a soil conditioner. South Africa is concerned with the hazards produced by sludge disposal, especially the pathogen, Ascaris. Legal provisions are available for controlling sludge disposal and preventing water pollution from this source, but to date no regulations have been made. Reasons for this are: (1) the paucity of scientific knowledge, especially on a local basis, and (2) a preference for slowly evolving guidelines, rather than strict statutes. Raw or primary sludge may not be used for agriculture, except as a compost supplement. Secondary sludge is limited to crops not eaten raw by humans and to some parks and sports fields under development. Tertiary sludge application is less restricted; sludge treated with advanced methods may be used anywhere with proper monitoring. (Cassar-FRC)

THE USE OF SEWAGE SLUDGE IN AGRICULTURE,
Water Research Centre, Stevenage (England).
E. G. Coker.
Water Science and Technology, Vol 15, No 1, p 195-208, 1983. 2 Tab, 52 Ref.

Descriptors: *Land disposal, *Sludge disposal, Agriculture, Land reclamation, Reviews, Soil amend-

ments, Soil properties, Water pollution prevention, Nutrients, Fertilizers, Nitrogen, Phosphorus, Organic matter, Sludge utilization, Fate of pollutants, Pathogens, Heavy metals, Metals, Toxicity.

The use of sewage sludge in agriculture is reviewed. Prior to the 1960's there was little enthusiasm for applying sludge to farm soils and little perception of its benefits. The major components in sludge useful in agriculture are organic matter, nitrogen, and phosphorus. The amount and chemical form of nitrogen and phosphorus varies with the type of sludge. Phosphorus content of the sludge can reach 18% as P205 in treatment processes designed to remove phosphorus. Use of sludge in agriculture is limited by the danger of polluting surface and groundwater with N, P, or pathogens. Guidelines for sludge application rates have been developed by countries according to their attitudes toward pollution. Among the trace elements which may be toxic at high accumulations are Zn, Cu, and Ni (phytotoxic) and Cd, Cu, Mo, Se, As, F, Pb, and Cr (harmful to humans and farm animals). Pathogens of concern are Ascaris, Salmonella in cattle yards, and human-beef tapeworm. Contact with pathogens is minimized by lagooning of sludge for 2 years, mesophilic anaerobic digestion of sludge, mechanical cultivation of fields, prevention of grazing on sludged fields for 3 weeks after sludge application, and choosing crops more suitable for growing with sludge (grains, fodder, and grasses). Sludge is also useful in reclaiming derelict land, such as waste tips, pits, and quarries, and in afforestation. (Cassar-FRC)

SEA DISPOSAL OF SLUDGE--THE U. K. EXPERIENCE,
Thames Water Authority, London (England).
H. Fish.
Water Science and Technology, Vol 15, No 1, p 77-87, 1983. 1 Fig, 2 Tab, 11 Ref.

Descriptors: *Sludge disposal, *Ocean dumping, *United Kingdom, International agreements, Monitoring, Water pollution effects.

Sludge disposal to the sea began on a large scale in the United Kingdom in 1889. Control measures were instituted in the 1960's; full licensing control, in 1974 (Dumping at Sea Act). Each year 10.5 million wet tons (300,000 dry tons) of sludge is disposed of in the sea, 95% by ship and the remainder by pipelines. The outer Thames Estuary receives 45% of the sludge. Present operations of sea disposal of sludge do not seriously affect the marine environment. Nitrogen and phosphorus levels at dump sites are sometimes twice that of unaffected water but are still much less than in the Mersey Estuary, heavily polluted with industrial discharges. Several mechanisms control sea disposal; international conventions (Oslo and London) and supervision by the Minister for Agriculture, Fisheries and Food. Metals concentrations in sewage sludge have dropped dramatically since 1974 as a result of the water authorities' monitoring of industrial wastewaters entering the treatment systems. It is recommended that sea disposal of sewage sludge be continued and expanded in the United Kingdom where economically and environmentally appropriate. (Cassar-FRC)

AGRICULTURAL UTILIZATION OF SEWAGE SLUDGE IN THE U.K.,
Anglian Water Authority, Huntingdon (England).
P. J. Matthews.
Water Science and Technology, Vol 15, No 1, p 135-149, 1983. 5 Tab, 10 Ref.

Descriptors: *Sludge disposal, *Land disposal, *Agriculture, Metals, Heavy metals, Nitrogen, Phosphorus, Nutrients, Fertilizers, Pathogens, Fate of pollutants, Aesthetics, *United Kingdom, Public health, Sludge utilization.

In the United Kingdom about 45% of sewage sludge is applied to agricultural land. For this use several factors are important: chemical quality (especially metals), microbiological quality, esthetic quality, marketability, and reliability of treatment and disposal processes. A table lists the acceptable limits of application for each toxic element. Cadmium is of greatest concern because it is toxic to humans. Zn, Cu, and Ni are phytotoxic in high concentrations. Pathogens of primary concern (salmonellae, intestinal parasites, particularly human-beef tape worm, and potato cyst nematode) have caused problems in only a few cases (not in humans) as a result of poor operational practices. Complaints from the public regarding odors may be minimized by considering wind direction during application, avoiding residential areas, plowing immediately after application, and careful choice of tanker routes. A table lists 11 types of sludge from liquid raw to mesophilic anaerobic digested and the acceptable uses for each. Nutrient contents (N, P, K, Ca, and Mg) of 5 types of sludges are listed on a % dry sludge solids basis. (Cassar-FRC)

SEWAGE SLUDGE HYGIENISATION BY GAMMA RAYS: AN OVERVIEW,
H. Herrnhut.
Water Services, Vol 86, No 1041, p 539, 1982. 1 Fig, 3 Ref.

Descriptors: *Sludge disposal, *Wastewater treatment, *Irradiation, Sludge thickening, Dewatering, Bacteria, Fecal coliforms, Salmonella, Public health, Land disposal.

Anaerobically stabilized sludge is irradiated at a Sulzer gamma irradiation plant in Munich. It is first filled into an above ground metering silo, from where it is passed into the irradiation shaft and then circulated for a fixed time by pumps taking it past the radiation source many times. A dose of 3000 Gray is sufficient to kill disease germs. Together with the activity level of the sources, the dose determines the duration of irradiation, after which the sludge is discharged by pumping. The cobalt-60 sources employed are accommodated in the double wall of a central tube in the irradiation shaft. They are cooled continuously with water in a separate circuit and monitored for leakage. After irradiation the total count of bacilli and Enterococci is reduced by 2 log on the average, and Enterobacteriaceae by 5 log. The counts of fecal bacilli and Salmonellae reduced by gamma irradiation do not increase again on thickening in the dry beds. The effects of irradiated sewage sludge on soils and plants are extremely favorable. Nutrients and trace elements present can be used directly by plants and also influence a number of soil factors. When conventional processes are replaced by irradiation, as a rule the input of primary energy is reduced too. The irradiation plant requires only electrical energy, whereas conventional processes usually consume heat also. (Baker-FRC)

IN-SITU AND ON-SITE BIODEGRADATION OF INDUSTRIAL LANDFILL LEACHATE,
Rutgers - The State Univ., New Brunswick, NJ. Dept. of Chemical and Biochemical Engineering.
R. C. Ahlert, and D. S. Kosson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-136787, Price codes: A03 in paper copy, A01 in microfiche. U.S. Dept. of the Interior, OWP. Center for Coastal and Environmental Studies Completion Report, June 1983. 21 p, 9 Fig, 4 Tab, 10 Ref. OWRT A-062-NJ(1), 14-34-0001-1132.

Descriptors: Industrial wastewater, *Leachates, *Biodegradation, Wastewater renovation, *Landfills, Soil bacteria.

Leachate from industrial landfills threatens surface water and groundwater quality and can pose significant management problems. In-situ and on-site treatment processes avoid the economic and technical disadvantages, as well as environmental risks, incurred by transport of this type of hazardous material to alternate treatment facilities. An in-situ/on-site treatment process has been developed utilizing biodegradation by a mixed microbial population, subsequent to lime flocculation pretreatment. Biodegradation is viewed as occurring in the landfill itself or in an adjacent soil system. To investigate the proposed treatment process, scale field experiments have been designed carried out. A pilot-scale field installation, co ing of six soil columns, two feet in diameter five feet deep, have been exposed to leachate cation under natural environmental conditions periments were conducted using specimen sandy loam and clay loam soils. The experi were designed for complete effluent recover lowing material balances. Vacuum was appli the base of each column, balancing capillary f and simulating natural drainage and water r tion. Variables included hydraulic, organic ca and nutrient loading rates, soil type and env mental conditions. The field experiment was ated for 169 days in 1982. Influent flow averaged about 10 liters/sq. meter/day. L volumes were recovered fully, except for expe minimal losses due to evaporation. Overall or carbon removal exceeded 90%. Reduction excess of 95% were readily attainable.

DESORPTION OF COMPOUNDS DURING ERATION OF GAC ADSORPTION SYSTE
Illinois Univ. at Urbana-Champaign. Dept. of Engineering.
W. E. Thacker, V. L. Snoeyink, and J. C. Crittenden.
Journal of the American Water Works Ass ation, Vol 75, No 3, p 144-149, March, 1983. 8 7 Tab, 22 Ref.

Descriptors: *Activated carbon, *Organic c pounds, *Desorption, Adsorption, Model stu Mass transfer, Hydraulic loading, Chlorinated drocarbons, Equilibrium, Water treatment.

Desorption of organic compounds from gran activated carbon was studied with a verified m ematical model to evaluate factors caused by duction in influent concentration or by complet Compounds chosen for study were chloroform bromodichloromethane. For desorption resul from a decline in influent concentration the ove rate of adsorption decreases with increasing car particle size and decreasing surface diffusivity, transfer coefficient, equilibrium capacity, isoth slope, and bed length. Higher hydraulic loadi produce a slower rate expressed as mass deso per bed volumes passed and a faster rate expres as mass desorbed per time. For desorption res ing from competition, the extent of overshoot creases with decreasing surface diffusivity, transfer coefficient, and bed length, and increas hydraulic loadings and particle size. Basically, proved mass transfer leads to faster or grea desorption. A decline in influent concentration competition can produce effluent concentrati greater than influent concentrations for a sign cant period of time, possibly several weeks. system designated for good adsorption is likely to desorb efficiently. HYDRAULIC AND GEOLOGICAL PROBLEMS OVERCOME AT BOBCAYGEON'S WATER AND SEWAGE TREATMENT PLANTS,
P. J. McGrenere.
Water and Pollution Control, Vol 121, No 1, p 12-13, January/February, 1983.

Descriptors: Water treatment, Wastewater treatment, Bobcaygeon, *Ontario, Aeration.

A water treatment and wastewater treatment system was designed for Bobcaygeon, Ontario, a resort area with variable population, located on a thin layer of till overlying bedrock. Part of the village is located on three small islands made from fill dredged out of the Trent Canal. The existing diatomaceous earth water treatment plant is used during low demand periods in winter. Two package plants (contact zone, tube settler clarifier and dual media self backwashing filters) go on stream for summer visitors. The wastewater treatment plant consists of two separate extended aeration units. Both are used in summer, one in winter. The hydraulic grit removal channels and outfall are common to both plants. The fissured limestone under the facility was capped with concrete, and urethane insulation was installed to prevent frost heaving. Final costs for the project, serving 5600 persons in the summer, were $11.2 million. (Cassar-FRC)

CLINOPTILOLITE IN DRINKING WATER TREATMENT FOR NH4+ REMOVAL (UTILISATION DE LA CLINOPTILOLITE EN POTABILISATION DES EAUX--ELIMINATION DE L'ION NH4+),
Rennes-1 Univ. (France). Lab. of the Chemistry of Water and the Environment.
M. Gaspard, A. Neveu, and G. Martin.
Water Research, Vol 17, No 3, p 279-288, March, 1983. 12 Fig, 3 Tab, 5 Ref.

Descriptors: *Ion exchange, *Ammonium, *Water treatment, *Clinoptilolite, Hardness, Cations, Zeolite.

Ion exchange was used to remove ammonium ions in drinking water treatment process. Clinoptilolite, a natural cation zeolite, had a small ammonium ion exchange capacity compared with its total capacity of 2.17 meq per g. In a soft water (35-50 mg per liter Ca) the practical ion exchange capacity was 0.06 and 0.108 meq per g for ammonium concentrations of 1 and 2 mg per liter, respectively. The treated volume of water to breakthrough, defined at 0.5 mg per liter ammonium, was > 720 bed volumes. Capacities for hard water treatment were less. Upflow regeneration proved more effective than downflow regeneration in reducing ammonium leakage. Pilot tests showed an ammonium leakage of 0.2 mg per liter and a treated volume to breakthrough (0.5 mg per liter) of 750 bed volumes for a 2 mg per liter ammonium influent. After three regenerations in a second column performance decreased by 25%; ammonium leakage increased but remained less than 0.5 mg per liter. (Cassar-FRC)

PROVING THE POINT FOR DISSOLVED AIR FLOTATION IN POTABLE WATER PLANT.
Water Sciences, Vol 84, No 1009, p 150-151, March, 1980.

Descriptors: *Flotation, *Aeration, *Water treatment facilities, Potable water, Dissolved air flotation, Glendye Treatment Plant, Scotland, Bewl Bridge Water Treatment Works, *England, Flocculation, Filtration.

An article published in Water Services, Vol 84, No 1006, p 19, January, 1980, described the Bewl Bridge water treatment plant as the first of its kind to use dissolved air flotation. The present article describes earlier applications of DAF. Although the Bewl Bridge plant was the first to be designed and built from conception around this process, Water Management Limited was the first company to introduce DAF on a commercial scale. The first DAF plant of this company was installed in 1975 at the Glendye Filter Station near Aberdeen, Scotland. The high color of the raw (peaty) water at Glendye required that alum flocculation be supplemented with dissolved air flotation. About 8 potable water plants are currently in operation. Relocatable package DAF plants are now available. These are quickly installed and may be moved as needed. DAF is also used in wastewater treatment. High throughput is possible, and microprocessor control has been implemented. (Cassar-FRC)

EFFICIENCY OF POINT-OF-USE TREATMENT DEVICES,
Everpure, Inc., Westmont, IL.
P. Regunathan, W. H. Beauman, and E. G. Kreusch.
Journal of the American Water Works Association, Vol 75, No 1, p 42-50, January, 1983. 12 Fig, 10 Tab, 15 Ref.

Descriptors: *Water treatment, *Activated carbon, *Carbon filters, *Membrane filters, *Reverse osmosis, *Performance evaluation, Suspended solids, Coliforms, Organic compounds, Pesticides, Adsorbents, Potable water, Filters, Filter media.

The performance efficiency of two point-of-use water treatment devices was evaluated in a barrage of testes. One device consisted of a granular activated carbon bed and a precoat filter, while the other was made up of a reverse osmosis (RO) unit, a prefilter and two granular carbon adsorption units. The granular-precoat device was successful in removing 80-90% of the chloroform and carbon tetrachloride from spiked samples for at least 3700 liters of treated water, while the RO unit system removed 95-97% of trihalomethanes and chloroform from spiked samples for at least 4900 liters of treated water. Point-of-use treatment devices were also capable of removing large amounts of pesticides from spiked treated water samples, but in the removal of several inorganic contaminants, a steady state was reached within the first hour of operation for RO modules. RO and granular precoat devices were very efficient at removing asbestos fibers, protozoan cysts and volcanic ash from treated water samples. Evidence is presented to show that precoat carbon filters do not consistently yield significantly higher levels of bacteria compared with influent levels. In RO-carbon devices, higher levels of indigenous organisms can be reduced by flushing 3.7-7.5 liters of water through the system. Both the granular-precoat device and the RO-carbon system did not encourage the growth of Escherichia coli, even under quiescent conditions. It was concluded that, if properly used, point-of-use treatment devices could effectively supplement centralized water treatment systems. (Geiger-FRC)

DISINFECTION, WATER QUALITY CONTROL, AND SAFETY PRACTICES OF THE WATER UTILITY INDUSTRY IN 1978 IN THE UNITED STATES,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Civil Engineering.
R. C. Hoehn, and J. D. Johnson.
Journal of the American Water Works Association, Vol 75, No 1, p 51-56, January, 1983. 17 Tab, 3 Ref.

Descriptors: *Drinking water, *Water quality control, *Disinfection, *Chlorination, *Surveys, *Utilities, *Water treatment, Data collections, Chlorine, Organic compounds, Water quality, Turbidity.

Answers to questionnaires sent to more than 300 water utilities in March of 1978 were examined to gain information of disinfection, water quality control and safety practices before making treatment

modifications to control trihalomethane (THM) levels in drinking water. Results showed that high levels of gaseous chlorine were being used at more than one point by most utilities, but one-third of the respondents indicated that chlorine was only applied in the distribution system. Most respondents reported poor control of chlorine residuals. The majority of utilities surveyed made no attempt to differentiate between free and total chlorine residuals; the most commonly used method of detection was DPD technique. In 25% of the utilities responding, chlorine-contact times were usually less than 12 minutes. Less than half of the 332 utilities responding used the standard plate count for reporting bacteriological quality. Of those that did, very high bacteria levels were reported. In 20% of 123 systems, chlorine demand was over 5 milligrams/liter, and iron and manganese levels were high, while turbidity was generally quite low. Few utilities surveyed practiced dechlorination. (Geiger-FRC)

SURVIVAL OF SOME FAECAL INDICATOR BACTERIA IN DRINKING WATER,
Biological Research Center, Baghdad (Iraq). Dept. of Environmental Pollution.
S. F. Jazrawi, and A. K. Al-Hindawi.
Journal of Environmental Science and Health, Part A, Vol 17, No 6, p 789-796, 1982. 3 Tab, 7 Ref.

Descriptors: *Chlorination, *Bacteria, *Water treatment, Baghdad, *Iraq, Turbidity, Coliforms, Streptococcus, Fate of Pollutants.

The length of time required for complete kill of indicator bacteria, E. coli and Streptococcus fecalis, in Baghdad, Iraq, water at the highest chlorine dose (0.8 mg per liter of chloride of lime) was 2.0 and 0.5 hours, respectively. Since the residual chlorine in city water was 0.1-0.4 mg per liter, the currently used chlorine doses will have to be increased to provide clean and safe water. Raw water samples were high in turbidity (132 NTU). (Cassar-FRC)

INSTRUMENTATION, TELEMETRY AND AUTOMATION: STANDARDS FOR WATER INSTRUMENTATION,
Northumbrian Water Authority, Gosforth (England).
D. G. Hall.
Water Services, Vol 86, No 1042, p 583-584, 586, 1982. 1 Fig.

Descriptors: *Standards, *Measuring instruments, Planning, Water management, British Standards, Regulations, Water quality standards, Design standards, Specifications.

The availability of well proven standards is fundamental to good practice and essential for manufacturers and users alike in the field of measurement. A British Standard applied to instrumentation serves the needs of the user related to the physical phenomenon to be measured, comprises the statement of the needs of the user to the manufacturer to show him the expectation of the user, and should be used by the manufacturer to declare to the purchaser that his instrument has been constructed so that it will produce the data he requires at the level of quality he needs. The procedure to be followed in developing a standard is briefly described. Since the development and publishing of an international standard takes up to five years, those drafting the standards must have at least ten year horizon in view. (Baker-FRC)

THE DYNAMICS OF GROWTH, THE EFFECTS OF CHANGING AREA AND NITRATE UPTAKE BY WATERCRESS NASTURTIUM OFFICINALE R. BR. IN A NEW ZEALAND STREAM,
Department of Scientific and Industrial Research, Taupo (New Zealand). Ecology Div.
C. Howard-Williams, J. Davies, and S. Pickmere.
Journal of Applied Ecology, Vol 19, No 2, p 589-601, August, 1982. 6 Fig, 4 Tab, 29 Ref.

Descriptors: *Nitrogen removal, *Nitrates, *Watercress, *Water quality, Streams, Water quality control, Plant growth, Seasonal variations, Nutrients, Nutrient uptake.

The growth of watercress in a stream was related to the seasonal removal of dissolved nitrogen and its incorporation into plant biomass. The maximum relative production rate occurred in mid-summer, being 0.0569 g/g/day. Leaf tissue and root tissue both increased early in the growing season, but in late summer and winter plants had a high proportion of stem, up to 60%. The changing area of the plant population complicated calculations of plant production and the interpretation of production rate/mean monthly quadrat biomass ratios. The same factor also affected the calculation of nutrient uptake. In mid-summer the field measurements of nitrogen uptake by plant showed that 1.140 g N/sq m/day was accumulated. A pattern of nitrate-nitrogen loss from the stream water was demonstrated; this loss could all be accounted for by watercress uptake, which exceeded (to a greater or lesser extent depending on the effect of changing area) the loss from the stream. The nitrogen-rich soils of the cress beds could provide the deficit. Very fast growth rates and a high nitrogen affinity make watercress an ideal plant for stripping nitrate from stream water. However, nitrate uptake is a summer phenomenon only, and rapid decomposition rates of cress suggest that much of the stripped nitrogen will eventually be returned to the water. Denitrification in the Whangamata cress beds does occur, but this apparently accounts for a small portion of the nitrate lost from the stream during summer. (Baker-FRC)

ESTABLISHING STANDARDS TO CONTROL DIRECT AND INDIRECT DISCHARGERS.
Clearwaters, Vol 12, No 3, p 5-8, 1982. 1 Ref.

Descriptors: *Water pollution control, *Standards, Water quality, Water quality control, Water quality standards, Legislation.

In order to achieve the goals of the Clean Water Act, certain effluent limitations must be based on water quality standards. Only through regulating dischargers on the basis of the needs of the receiving water can a reasonable, cost effective approach to water pollution control be implemented. Some of the strengths and weaknesses of the existing standard-setting process under the present Clean Water Act are described. It is suggested that Congress should give priority to establishing a single system for controlling direct dischargers and a second system, if needed, for indirect dischargers. Three possible systems considered include the use of water quality standards, a technology-based categorical standard, and pollutant-specific guidance systems. Since it would take at least 10 years to fully implement a water quality-based system, the NYWPCA believes that, in the interim, the Act should mandate that S/NPDES permits be issued with effluent limitations that are based on PS criteria. Not only will such an interim approach enable maximum utilization of existing data while assuring an almost immediate improvement in the quality of treated wastewater discharged nationwide, but it will also provide a common ground for individual permit negotiation. SCHENECTADY COUNTY AQUIFER PRES VATION STRATEGY PROGRAM.
Schenectady County Planning Dept., NY.
Final Report, August 1980. 32 p, 14 Fig, 1 App

Descriptors: *Aquifer management, *Aquifer c acteristics, *Groundwater storage, *Water sources development, Flood plain managem Planning, Water management, Regional deve ment, Rivers, Water supply systems, Water sup Water consumption, *New York.

Five Schenectady County municipalities and n than 80% of its residents rely entirely on subsurface gravel deposits of the Mohawk Va for their public water supply. This aquifer area been increasingly prone to development due to construction of an interstate highway and the p sures of suburban expansion. A report compl in 1978 recommended measures to preserve critical aquifer areas. A subsequent report in described the existing and projected best uses each parcel and the costs to either purchase restrict the easements to each. The current aqu preservation strategy suggests preserving th areas that are the most important to existing future public water supplies. This report list wide range of actions that must be instituted protect the aquifer from contamination originat outside of the critical areas. The implementat plan recommendations include creation of a cou water council, upgrading the classification of Mohawk River, flood plain management, s source designation for the aquifer, collection letters of record for land parcels, and spill clea coordination. ision making, Preference order dynamic pro-
ming, Multi-objective planning, Vector opti-
ion.

r resources agencies are operating and plan-
in an environment which is complicated by
ple, oftentimes conflicting objectives, uncer-
es and risks. The situation is especially critical
od control because of the magnitude of the
damages, the number of conflicting objec-
and impacted groups, and the inherent mete-
gical uncertainties. Floods are the most wide-
d geophysical hazard in the United States and
account for greater average annual property
than any other single geophysical hazard.
realization among others has led to an increas-
wareness and interest in the role of nonstruc-
measures such as floodplain zoning, land use
ation, insurance, and warning as an important
integral part of any overall flood damage
ation program. However, determining 'opti-
nixes of adjustments to floods is very difficult
se of the number of conflicting water re-
es objectives, the degree of interdependence
een the structural and nonstructural measures,
ultitude of feasible combinations of structural
onstructural measures which must be consid-
over time and space. This report discusses
ple objective optimization and decision
g in the context of flood control and devel-
dynamic approach which involves the amal-
tion of the often disparate fields of utility
y and vector optimization into an integrated
odology based on the notions of 'preference
dynamic programming,' a recursive algo-
not requiring the existence of a real-valued
n function. This report also discusses practical
involved with the use of the method as well
her implementation and computational details.

anagement model was developed for determin-
optimal mixes of recreation activities at public
king water reservoirs. Quabbin Reservoir, lo-
d in central Massachusetts, served as a case
y for the model. An interdisciplinary research
was formed to study (1) the impact of select-
ecreation activities on water quality, (2) public
and and willingness to pay for selected recrea-
activities at Quabbin, (3) the carrying capacity
ential of the reservoir and (4) the cost-benefits
ciated with increases in recreation at Quabbin.
study variables were integrated into a quadrat-
ic programming model producing optimal recreation activity mixes as outputs. The optimal mix included hiking, fishing, picnicking (presently permitted activities), canoeing, sailing and swimming (presently prohibited activities). These activities were found to be cost-effective (assuming the use of reasonable entrance fees) and not deleterious to water quality. Nutrients, particularly from wastewater, should not be permitted to enter the water since current phosphorous levels may be at a critical point. This can be assured with proper precautions and effective management techniques. The model was sensitive to management objectives; recommendations were limited to activities that would not lower the existing high quality of Quabbin water.

6B. Evaluation Process

REAL TIME ADAPTIVE CLOSED LOOP CONTROL OF RESERVOIRS WITH THE HIGH ASWAN DAM AS A CASE STUDY,
Massachusetts Inst. of Tech., Cambridge. Ralph M. Parsons Lab. for Water Resources and Hydrodynamics.
R. L. Bras, R. Buchanan, and K. C. Curry.
Water Resources Research, Vol 19, No 1, p 33-52, February, 1983. 16 Fig, 7 Tab, 13 Ref.

Descriptors: *Streamflow forecasting, *Reservoir operation, *Flood control, Aswan Dam, Egypt, Model studies, Stochastic hydrology, Irrigation, Toshka Spillway, Multipurpose reservoirs.

An algorithm incorporating real time streamflow forecasts into reservoir operation was used to predict inflows into the High Aswan Dam. This adaptive control technique can handle situations where streamflow transition probabilities and system objectives are continuously updated and changing over finite transient periods before achieving steady state conditions. A comparison of results obtained with a steady state stochastic dynamic programming approach was made with the heuristic operational policy which is used at the dam. Improvements in system performance depended on the system configuration. With operation of the Toshka spillway, the new scheme showed little improvement relative to the steady state scheme. For no Toshka spillway and annual abstractions from the Sudan of 16.5 billion cu m, considerable improvements were demonstrated using the new scheme. The most significant benefit is likely to be improved flood control. Streamflow forecasts for the beginning of a drought period are particularly important because they may allow the release of more water than needed to meet the irrigation requirements, thereby preparing storage space for high inflows which may follow. EVALUATION OF ECONOMIC RETURNS FROM INVESTMENT IN DOMESTIC RURAL WATER DEVELOPMENT,
South Dakota State Univ., Brookings. Dept. of Economics.
R. Hoffman, A. Lundeen, and R. Green.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-120831. Price codes: A05 in paper copy, A01 in microfiche. Water Resources Institute Completion Report, July 1983. 59 p, 20 Tab, 13 Ref, 1 Append. OWRT A-080-SDAK(1), 14-34-0001-2144.

Descriptors: *Domestic water, *Stock water, Water resources development, *Economic impacts, *Rural water systems, Livestock productivity, Agricultural productivity, Domestic rural water development, *South Dakota.

The impacts of a rural water system on livestock productivity and production in two counties in South Dakota were investigated. Both members and nonmembers of rural water systems were surveyed to learn if there were differences between the two groups in number of livestock on hand, stability in numbers of livestock, effects of drought on livestock numbers, and changes in productivity because of an assured supply of quality water. Reported incidences of livestock producers being forced to sell or board out livestock during drought were few and about equal for nonmembers and members. Rural water system members held a higher absolute number of cattle in Tripp County and all livestock in Moody County. However, the differences were significant only for milk cows and beef cows in Moody County for one year in the surveyed period. Tripp county nonmembers had a significantly higher number of breeding hogs on hand in all four surveyed years. No statistically significant differences were found between the groups in changes in number of livestock. About one-quarter of the rural water system members reported substantial increases in average daily gain due to the availability of good quality water. Approximately 10% reported decreased newborn mortality rates or decreased medicinal costs.

THE RED RIVER GORGE: THE EXISTENCE OF 'RECREATIONAL NICHES' AND THEIR MANAGEMENT IMPLICATIONS,
Kentucky Water Resources Research Inst., Lexington.
S. E. Alexander, B. R. Dewalt, and E. Scott.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-120914, Price codes: A11 in paper copy, A01 in microfiche. Research Report No 145, September 1983. 232 p, 4 Fig, 49 Tab, 54 Ref, 2 Append. OWRT A-079-KY(2), 14-34-0001-9019(FY 79), 14-34-0001-0119(FY 80), 14-34-0001-1119(FY 81).

Descriptors: *Recreation facilities, *Recreation demand, *Recreation, Wild rivers, Tourism, *Red River, Kentucky, River recreation management, Social carrying capacity, Recreational niches, Visitor preferences.

This report examines the recreationists' socio-demographic characteristics, the recreational activities engaged in, their density tolerance levels, and their preferences for development of the Red River Gorge, Kentucky. Eleven 'recreational niches' (defined as a specific location within a recreation area occupied by visitors pursuing different kinds of leisure-time activities) were identified. Preservation of the niches are recommended as a means for maintaining both the ecological and social diversity of the Red River Gorge. Substantial increases in visitation has resulted in not only severe environmental degradation to the area but extensive overcrowding as well. These trends are presently overtaxing the management capabilities of the area. The pressing issue is how to effectively manage this area to preserve both its ecological and social attractiveness.
W84-00441

THE DREDGING DILEMMA: SYSTEM PROBLEMS AND MANAGEMENT SOLUTIONS.
New England River Basins Commission, Boston, MA.
Report, September 1981. 26 p, 14 Fig.

Descriptors: *Dredging, *Planning, *Harbors, *Coastal engineering, *Multiobjective planning, *Management planning, *Long-term planning, Waterfront facilities, Interagency cooperation, Evaluation, Economic aspects, Comprehensive planning, Disposal sheds.

While efficient harbor facilities contribute to the economic base of coastal regions, management of dredging has become a controversial public issue. In the private and public sectors there is currently no process for arraying and assessing future demands for dredging. This study examines dredging as a set of interrelated functions directed to a specific end. Three basic flaws, endemic to the

dredging system as a whole, are identified: (1) unclear objectives; (2) isolated reviews of dredging proposals; and (3) limited evaluations. A proposed solution is a management planning process that emphasizes interagency cooperation and the establishment of agreed-upon objectives to guide dredging decisions, and to provide a basis for evaluating the results of dredging initiatives. In addition to defining objectives and setting priorities, dredging management could be improved by identifying disposal sheds, developing sediment characterization criteria, designating public disposal sites, establishing disposal site management methods, and evaluating and updating the management program on a regular basis. Specifically regarding the dredging of New England and Long Island Sound waters, there are eleven feasible disposal sheds to which dredging management could be applied. (Garrison-Omniplan)

PROJECTED DEMANDS AND SUPPLIES OF WATER UNDER ALTERNATIVE ENERGY AND AGRICULTURAL DEVELOPMENT SCENARIOS IN THE GREEN RIVER DRAINAGE OF WYOMING,
Wyoming Univ., Laramie. Coll. of Agriculture.
D. R. Franklin, J. J. Jacobs, and P. J. Farris.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-132471, Price codes: A04 in paper copy, A01 in microfiche. Water Research Center Completion Report, August 1983. 53 p, 1 Fig, 9 Tab, 48 Ref, 1 Append. OWRT A-039-WYO(1), 14-34-0001-2154.

Descriptors: Water conservation, Water allocation, Saline water, Water resources development, *Water demand, *Water supply, Irrigation water, Industrial water, *Economic impact, Agricultural development, Energy development, *Wyoming, *Green River Basin.

Five alternative salinity management policy and agricultural growth scenarios were analyzed for the Green River drainage in Wyoming. A linear program model was developed that evaluates the economic impacts of water development with salinity management policies. The results indicate that energy development can take place without imposing undue salinity damage cost downstream if no additional development occurs downstream from Wyoming. However, large scale agricultural development could increase salinity damage cost in the form of reduced energy production and/or monetary cost to the State.

6C. Cost Allocation, Cost Sharing, Pricing/Repayment

FACILITIES NEEDS SURVEY OF COMMUNITY PUBLIC WATER SYSTEMS,
New York State Dept. of Health, Albany. Bureau of Public Water Supply Protection.
P. A. Chiefari.
Report, April 1983. 64 p, 4 Fig, 33 Tab, 3 Append.

Descriptors: *Project planning, *Distribution patterns, *Water quantity, *Water supply, Aqueducts, Urban planning, Operating costs, Projections, Operating policies, Water rates, Water distribution, *Capital costs.

Many water systems in New York State suffer from capital and physical deficiencies. To correct these problems, it is necessary to determine their extent and estimate the cost of correction. A survey using personal interviews and mailed questionaires was conducted by the New York Department of Health. In New York State, 1,420 community public water supplies provide 16.5 million people with 3.7 billion gallons of water a day. The total statewide funding need was found to be $6.8 billion, with $4.2 billion required by New York City. The highest priority in preferred spending was given to distribution system improvements, with treatment, storage, and source a nearly equal second. Additional areas examined in interviews with water system personnel included water rates, metering and operations and maintenance. In terms of capital cost to remedy these needs, problems arise because the component costs are large and such costs weigh heavily against smaller systems whose per user annual assessments are high. Additionally, certain projects are so expensive that even the very largest systems would have difficulty in building them without federal assistance. A proposed water project for New York City, for example, is estimated to cost $3.4 billion. (Garrison-Omniplan)

DISCUSSION 'MUNICIPAL WATER SUPPLY RESTRICTIONS AS URBAN GROWTH CONSTRAINTS,' BY W. B. LORD,
Economic Research Service, Washington, DC. Natural Resource Economics Div.
R. L. Anderson.
Water Resources Bulletin, Vol 19, No 1, p 131-133, 1983.

Descriptors: *Water supply development, *Water demand, Denver, Colorado, Pricing, Water use, Municipal water.

In the original paper (Water Resources Bulletin, Vol 18, No. 2, p 271-277, 1982) the idea was presented that limiting water supply does not inhibit urban growth. Various studies were cited to show that growth occurs in areas where water supplies are limited. In an examination of residential use of water, the original author states that substantial savings in water use by householders. The argument is stated that industrial and commercial growth can be accommodated within existing municipal supplies if residential demands can be reduced. The discussant maintains that the suggestion to homeowners that lawns can survive on 70% of the water they are capable of taking up is illusory; that to put watering or waste of water on lawn watering on a gallon-per-day basis is clearly inaccurate and misleading, as residents in Colorado's Front Range cities water their lawns only rarely at present anyway; and that raising prices for water could turn out to be a lawn tax, with far reaching effects on the older, fixed-income area residents rather than on new members of the community. The discussant suggests that the Denver Water Board pursue its historic course of expanding the water supply. While this course has been criticized by certain environmental groups, the disrupting effects of this course are no worse and perhaps less burdensome than depriving urban areas of adequate water. (Baker-FRC)

DISCUSSION 'CONFLICT BETWEEN ESTABLISHMENT OF INSTREAM FLOWS AND OTHER WATER USES ON WESTERN STREAMS,' BY RAMOND L. ANDERSON,
Southern Methodist Univ., Dallas, TX. Dept. of Civil and Mechanical Engineering.
M. A. Collins.
Water Resources Bulletin, Vol 19, No 1, p 137-138, 1983. 2 Ref.

Descriptors: *Water resources development, *Legal aspects, *Water rights, Doctrines, Water demand, Recreational use.

The author of this discussion enlarges upon the theme of the main paper (Water Resources Bulletin, Vol. 18, No. 1, p 61-65, 1982) dealing with the problem of the attack on established appropriate rights and the appropriate rights doctrine itself by advocates of instream water use. Recent studies in Texas are cited to demonstrate the enhancement of natural conditions through appropriate water
agemment practices. Particular mention is m
the Possum Kingdom Reservoir constructed
Brazos River for the stated purposes of pre
tion and enhancement of fish and wildlif
recreation in generally recognized scenic
reaches below the reservoir. This dam, built
1930s, has enhanced downstream condition
nificantly over the years. While concern for
ational interests, in itself, is certainly accep
inadequate consideration of the impact of
ational objectives on other water uses, partic

Wetlands, Environmental effects, Seasonal v
ation, Planning, Groundwater management.

The West Coast (Florida) Regional Water Sup
Authority, formed in 1974, relies on extensive d
to provide water for the rapidly growing a
seasonally variable population of the St. Pete
burg-Tampa area. Precipitation (and the grou
water resource's response to it) varies widely, b
annually and seasonally. When new well fields
planned, the Authority must consider the availa
hydrogeological information, water demand,
fects on groundwater levels of the proposed wi
drawal rates, and effects on the ecosystems. T
planning procedure is illustrated in the develo
ment of the Crossbar Ranch well field. This i
volved hydrogeologic tests and computer mod
ing of the effects of different well locations
groundwater level. Monitoring programs conce
levels in the 1500 private wells and 105 wetlan
and lakes within 2 miles of the well field, histor
lake trends, sinkhole activity, runoff and strea
flow water budgets, and the aquatic and terrestri
habitats. Of the $16.3 million spent for the Cros
bar project, 12.5% was for investigations and ma
agement system instrumentation. (Cassar-FRC)

risdiction, State jurisdiction.

ecognized need for reform and the increasing
ral need for water may induce the federal
ernment to take on a greater role in western
r law in the future. This article analyzes the
nt to which the Rivers and Harbors Act can
should be used by the federal government to
nd its role in western water allocations. The
ry and development of western water law and
traditional role of the federal government in
ern waters is reviewed. The growing conflict
control of western waters and the possible
vation for an increased federal role is dis-
ed. This discussion focuses on the potential
icability of section 10 of the Act to state water
ations. Section 10 bars any unauthorized ob-
ctions to the navigable capacity of any waters
e United States and makes it unlawful to alter
nodify any navigable water without the ap-
al of the US Army Corps of Engineers. The
torial and subject matter jurisdiction of the
and the permit process are detailed. A close
ination is offered of California vs Sierra Club,
ch discusses specific issues left unresolved by
Supreme Court in that it refused to allow the
ntiffs the right to bring suit under the Rivers
Harbors Act. The article concludes with an
nination of the extent to which the Rivers and
ors Act can and should be used in the context
estern water allocation. (Baker-FRC)

OUNDWATER LITIGATION,
k Coll., New Brunswick, NJ.
Goldfarb.
er Resources Bulletin, Vol 18, No 5, p 899-900,

criptors: *Legal aspects, *Groundwater man-
ment, Supreme Court, Arizona, Nebraska,
er demand, Water use, Exportation, Aquifers,
er law.

US Supreme Court recently took action on
cases involving the regulating of transporta-
of groundwater by the states involved. Spro-
v. Nebraska was the more important, dealing
the constitutionality of a groundwater 'antiex-
ation' statute. Some antiexportation statutes
ibit any exportation of water. Others allow it
e recipient state has legislated reciprocal
s. Nebraska enacted a statute of the latter
, and the state Supreme Court upheld it, based
he view that groundwater is not an article of
merce. The US Supreme Court reversed this
, stating that groundwater overdraft is a na-
l problem and Congress has the power to deal
it on that scale. The second case, Town of
o Valley v. City of Prescott, raises questions
t the ownership of groundwater. The City
s 164 acres of land in the Valley. In 1948 the City drilled wells on some of its Valley property and began transporting groundwater through a 17 mile pipeline to its municipal customers. The Town of Chino Valley was incorporated in 1972 and began drawing groundwater from the same aquifer. The Town claimed the City was taking private property (groundwater) without just compensation. The common law doctrine of riparian rights in Arizona has been replaced by the appropriation doctrine except as regards percolating groundwater. Here the doctrine of reasonable use still applies. The state Supreme Court, and later the US Supreme Court upheld the decision, claiming that the overlying owner does not possess absolute ownership of groundwater but merely a right to the 'usufruct' (use) of the water, subject to state regulation. (Baker-FRC)

REPLY TO DISCUSSION 'POLICY PROBLEMS ASSOCIATED WITH WATERBORNE ASBESTOS', BY MICHAEL EDSON AND W. A. THOMPSON,
Iowa Univ., Iowa City. Dept. of Urban and Regional Planning.
M. F. Sheehan.
Water Resources Bulletin, Vol 19, No 1, p 127-130, 1983. 3 Fig.

Descriptors: *Asbestos, *Legal aspects, *Water pollution sources, Industrial wastes, Industrial discharges.

In this reply the author of the original paper (Water Resources Bulletin, Vol. 17, No. 2, p 275-279, 1981) deals with major points brought out in the discussion paper (Water Resources Bulletin, Vol. 19, No. 1, p 123-126, 1983). The original paper dealt with a temporary stay in discharges from the Reserve Mining Company into the environment, both air and water, of asbestos fibers. The discussion argues that the assertion of the original author that the temporary stay of the Appeals Court was based on the fact that the fiber levels were not occupational levels, that the low levels present could not be measured and therefore did not constitute a health risk, and that it was not known what level of exposure was actually unsafe, is incorrect. The original author replies that the decision clearly stated that the levels of contamination were not equivalent to the contaminated air found in an asbestos factory and the fibers ingested from the Duluth drinking water were not equatable to an occupational exposure level. That the levels of exposure were so low as to be unmeasureable as a health risk is stated in the original court's decision and the argument that this decision could not have been based on these facts but instead had to meet the four criteria set out in the rules for civil and apellate procedure is seen by the original author as a confusion of facts with procedural rules. Facts and procedures are not mutually exclusive in the law. Decisions of this sort must both have a factual basis and meet the rules of procedural due process. (Baker-FRC)

DISCUSSION: 'POLICY PROBLEMS ASSOCIATED WITH WATERBORNE ASBESTOS' BY M. SHEEHAN,
Arizona Univ., Tucson. Dept. of Philosophy.
M. Edson, and W. A. Thompson.
Water Resources Bulletin, Vol 19, No 1, p 123-126, 1983. 6 Ref.

Descriptors: *Water pollution sources, *Legal aspects, Liability, Torts, Asbestos, Policy, Public policy, Rights.

The discussants review and assess a presentation in Water Resources Bulletin, Vol 17, No 2, p 275-279, 1981 on the litigation arising out of the discharge of asbestos-like fibers into Lake Superior by the Reserve Mining Company. The most important aspect of the suit brought against Reserve was that public health and welfare were endangered through this discharging of asbestos-like fibers. The author of the original paper charges that the district court issued an injunction against Reserve's continued discharge purportedly on the basis of Section 504 of the Federal Water Pollution Control Act which permits injunctive relief when the public is faced with an imminent health hazard. However, in truth, the injunction was issued on the basis of the five complaints brought against the company and no determination that a hazard was imminent was made. A stay of the injunction was issued by a federal appeals court, but this was only a temporary stay, pending Reserve's appeal of the case on merits. The confusion of factual and normative issues is a dangerous flaw in argumentation. The charge of the original paper that by not regulating potentially harardous substances the government is contributing to economic inefficiency in the neoclassical sense is addressed by the discussants in stating that determinations of tort liability are not generally based on economic efficiency, but rather on considerations of justice and fairness with respect to compensation for harms incurred. The relevant claim would have been that not regulating the discharge of potentially hazardous substances constitutes a violation of certain principles of equity. (Baker-FRC)

WATER RESOURCES MANAGEMENT IN A FEDERAL SYSTEM: A COMPARATIVE ANALYSIS,
North Carolina State Univ. at Raleigh. Dept. of Political Science and Public Administration.
T. D. Edgmon.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-120864, Price codes: A10 in paper copy, A01 in microfiche. Water Resources Research Institute Report No 203, September 1983. 209 p, 43 Tab, 2 Fig, 87 Ref, 1 Append. OWRT B-135-NC(1), 14-34-0001-1254.

Descriptors: *Water management, *Decision making, *Institutional constraints, *Governmental interrelations, *Water policy, Institutions, Local governments, State jurisdiction, Water Resources development, Water supply, Political constraints, Political aspects, Policy making, Planning, Regional planning, Water districts.

The objectives of this study were to review existing information on the organization of state, regional, and local water supply systems, determine the existing pattern of state water management institutions, analyze the evolution of substate water supply organizations in the state of Florida, determine the existing pattern of water resources decision making and intergovernmental relations in North Carolina, and evaluate a set of institutional and organizational alternatives suitable for consideration by policy makers in North Carolina. The study identifies four major types of state water resources management organization: unified, federalist, home rule, and fragmented. A survey discovered that state regulation of consumptive water use is becoming universal, even in the absence of a federal policy and program to provide incentives and sanctions. Most states have implemented their water resource regulatory programs on a decentralized basis, relying on either established local water organization, creating field offices with local policy boards, or developing basin control areas. Data from two surveys was analyzed to portray the structure of municipal organization in water supply, local official perceptions of water supply issues, the structure and process of intergovernmental relations, and an evaluation of local official preferences for areawide strategies of water supply allocation. Local officials generally do not rank water supply problems as serious ones, and prefer that the state continue to play a facilitative role in water areawide approach, and consider county government as a viable institution for water allocation among competing urban interests.

Descriptors: Water supply, *Institutional constraints, Legal aspects, *Water districts, Political constraints, State jurisdiction, Feasibility studies, Financing, Urban planning, Community development, *Utility extension, Utilities, Potential water supply, *Urban areas, Water management.

Scattered rural towns are largely served by individual water systems. Urbanization fills the areas between older communities and requires system expansions that encourage the smaller systems to combine and search for larger, higher quality, and often more distant and costly supplies. The western states have established a variety of special water districts to serve growing metropolitan areas. Over the years, these districts have had a variety of experiences, both successes and failures, useful in guiding organizational arrangements for supplying water during periods of urban expansion. The large public water districts in Utah, Arizona, Colorado, Nebraska, Oregon, and South Dakota provided the experience data for this study. Applicable statutes were reviewed, and structured interviews were conducted with district officials. The special districts serving a number of communities have often responded to visions of pending water shortage by committing themselves, legally and financially, to major water projects. These obligations constrain the district's flexibility to adjust its water supply system to changes in demand and supply situations. The political commitment required for their formation also restricts thoughtful examination of system management alternatives because of fears that new options will erode public support to continuing repayment. State government needs to exercise its oversight responsibility in promoting harmonious coordination between districts and the communities they serve and in reviewing their fiscal management policies.

6G. Ecologic Impact Of Water Development

LAND USE, NUTRIENT YIELD, AND EUTROPHICATION IN THE CHOWAN RIVER BASIN,
North Carolina Univ. at Chapel Hill. Dept. of Environmental Sciences and Engineering.
N. J. Craig, and E. J. Kuenzler.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-120872, Price codes: A05 in paper copy, A01 in microfiche. Water Resources Research Institute Report No 205, North Carolina State Univ., Raleigh, August 1983. 75 p, 16 Tab, 23 Fig, 125 Ref. OWRT B-127-NC(13), 14-34-0001-0274.

Descriptors: *Nonpoint pollution sources, *Water quality, *Eutrophication, *Land use, *Agricultural runoff, *Nutrients, Rivers, Model studies, Watershed management, Nitrogen, Phosphorus, Forests, Cultivated lands, Cropland, Fertilizers, Drainage, Livestock, Animal wastes, Erosion control, Wetlands, Swamps, Cycling nutrients, Nutrient removal, Channeling.

Land use changes within the Chowan River watershed over the past three decades were determined to assess their potential impact on recent water quality degradation and eutrophication of the Chowan River. The amount of harvested cropland has remained constant, but yields from major crops have increased, due partly to increased fertilizer usage. There has been a large increase in artificial drainage on farms from 1940 to 1978, approaching 12% a year. Approximately 67% of the farmland in the North Carolina Chowan watershed is now drained versus 6% in Virginia. A 30% decrease in oak-gum-cypress forested wetland occurred in the N.C. Chowan basin from 1964 to 1974. Swamp forests remove an estimated 83% of the total N and 51% of the total P in streams passing through them. Mass balance models suggested that, of the annual nitrogen inputs to the Chowan River (6.94 x 10 kg N/yr), agriculture contributes 62%, forests and wetlands 21%, and point sources 17%. Of the annual potential phosphorus inputs (3.06 x 10 kg P/yr), agriculture contributes 72%, forests and wetlands 22%, and point sources 6%. Recommendations for reducing nutrient overloading to the Chowan River include use of agricultural Best Management Practices to avoid overloading of soil with fertilizer of animal wastes, and protection of swamp forests so that these wetlands can remove nutrients before they enter the river.

DDING SOME LIGHT ON TURBIDITY,
. Crossley.
er Services, Vol 86, No 1042, p 591-592, 594, . 7 Fig, 3 Tab.

Descriptors: *Turbidity, *Measuring instruments, Turbidimeter, Water quality, Wastewater treatment.

A brief history of the development of methods for measuring turbidity is given. Basic configurations for different types of turbidity measuring devices are described. In basic or probe type instruments, arrangements are made to remove the probe from the liquid and clean the glass manually. The probe is then immersed in a sample of liquid which contains a minimum of suspended solids, and the output from the detector is adjusted to give a zero reading. The probe is then replaced in the liquid and will indicate the obscuration, either in percentage obscuration or NTUs depending on the calibration of the instrument. Some designers of commercially available turbidimeters consider that fouling of the cell windows can cause inaccuracies, and rather than compensate for loss of light transmission, they prefer to provide a method of cleaning the windows. Virtually all modern turbidity meters operate on the principle of optical obscuration; and many designs have been introduced to compensate for aging of lamps and photodetectors and errors due to fouling of the cell windows. However, a few turbidimeters are available in which a different approach has been used. Models are available which are based on the nephelometric principle, with the detector unit totally submersed in the liquid. Still another design is based on the appearance of a final settlement tank as a deep black hole with no apparent bottom. If the tank appears to contain water or other fluid, then some suspended solids are present. (Baker-FRC)

HYDROLOGY OF AREA 15, EASTERN COAL PROVINCE, KENTUCKY AND TENNESSEE,
Geological Survey, Louisville, KY. Water Resources Div.
D. W. Leist, F. Quinones, D. S. Mull, and M. Young.
USGS Open-File Report 81-809 (WRI), January 1982. 81 p, 46 Ref.

Descriptors: *Hydrologic data, *Water quality, *Groundwater, Surface water, *Coal mines, Geohydrology, *Acid mine drainage, Soils, Floods, Low flows, Water use, Land use, *Kentucky, Eastern Coal Province, Cumberland River, Rockcastle River, Laurel River, Tennessee.

Area 15, in Eastern Kentucky and Tennessee consists of 3,095 square miles in the Cumberland, Rockcastle and Laurel River basins. The area is underlain by Permian, Pennsylvanian, Mississippian rocks. The Breathitt Formation of Pennsylvanian age crops out in about 75% of the area and contains most of the coal. About 22 million tons of coal were produced in the area in 1978, 52% from surface mines. The terrain is steep with acidic soils. Forestry and pastures are the principal land uses. Precipitation ranges from 47 to 54 inches per year, and the 24-hour 10-year frequency storm averages 4.5 inches. Flood prone areas along the rivers have been defined or can be determined from relations with drainage area and physiography. Low flows are poorly sustained, with most streams draining less than 100 square miles approaching a 7-day 10-year minimum flow of zero. Ground water is generally of good quality, although high iron concentrations are common. Sandstones are the principal aquifers. Water levels fluctuate seasonally, and yields of wells are usually less than 50 gallons per minute but range from about 1 to 250. Mine drainage affects the quality of streamflow at most sites in mined basins. Sulfate concentrations are as high as 1,000 milligrams per liter. Other constituents such as iron and manganese also occur in higher concentrations in waters of mined basins. Acid mine drainage generally is neutralized near its source. Most of the water in streams has pH values in the 7-8 range. (USGS)

WATER RESOURCES OF THE GIG HARBOR PENINSULA AND ADJACENT AREAS, WASHINGTON,
Geological Survey, Tacoma, WA. Water Resources Div.
B. W. Drost.
USGS Open-File Report 81-1021 (WRI), 1982. 148 p, 14 Fig, 1 Plate, 17 Tab, 21 Ref.

Descriptors: *Hydrologic data, *Surface water, Groundwater, *Hydrologic budget, Groundwater recharge, Aquifer characteristics, Saline water, Encroachment, *Washington, Gig Harbor.

The study area is a remnant of a glacial-drift plain nearly surrounded by marine embayments. A water-resources appraisal was made because the area is experiencing rapid population growth. Additional ground water is available for use in the study area. At least 11 cubic feet per second, five times the 1978 rate of use, can probably be obtained. Ground-water quality is generally very good, with minor problems of excess iron, manganese, dissolved solids, chloride, and coliform bacteria. Total flow through the hydrologic system is at an average rate of 254 cubic feet per second, which includes 93 cubic feet per second of ground-water recharge. (USGS)

HYDROLOGIC DATA FOR THE POTOMAC FORMATION IN NEW CASTLE COUNTY, DELAWARE,
Geological Survey, Dover, DE. Water Resources Div.
M. M. Martin, and J. M. Denver.
USGS Open-File Report 81-916 (WRI), 1982. 148 p, 80 Fig, 7 Tab, 40 Ref.

Descriptors: *Hydrologic data, *Groundwater, *Surface water, *Water quality, Wells, Pumpage, Water level, Aquifers, Transmissivity, Storage coefficient, Geohydrology, Chemical analysis, Hydrographs, *Delaware, New Castle County, Potomac Formation.

Hydrologic data for the Potomac Formation in New Castle County, Delaware, consists of records of historical ground-water pumpage, water levels, water quality, and surface-water discharge. Included are well records for 405 wells, and hydrographs

of water levels in 86 wells. Pumpage for 20 well fields are reported. Also included are stream-discharge hydrographs for 6 stations for water years 1979 and 1980, and historical low-flow measurements for 22 stations. In the analysis of 23 aquifer tests, transmissivity and storage coefficient values for the Potomac Formation range from 454 to 8480 square feet per day and 0.0026 to 0.000056, respectively. Vertical hydraulic conductivities of confining beds in the Formation range from 0.0083 to 3.2 feet per day. (USGS)

GEOHYDROLOGY OF PRINCIPAL AQUIFERS IN THE REPUBLICAN RIVER BASIN, KANSAS,
Geological Survey, Garden City, KS. Water Resources Div.
L. E. Dunlap.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $15.50 in paper copy, $2.50 in microfiche. USGS Open-File Report 82-79, 1982. 5 Sheets, 25 Ref.

Descriptors: *Aquifers, *Geohydrologic units, *Groundwater, Water table, Groundwater level, *Maps, Irrigation wells, Well yield, Hydrologic data, *Kansas, Republican River basin.

Principal aquifers in the Republican River basin in Kansas are unconsolidated alluvial deposits. One such aquifer is formed by the Ogallala Formation of Miocene age which covers most of the western part of the area. Because saturated thickness of the aquifer decrease northeastward, maximum yields to irrigation wells decrease in that direction from 2,000 to 500 gallons per minute. The Grand Island Formation of Pleistocene age occurs in an ancestral channel of the Republican River in northeast Jewell and northwest Republic counties. The maximum yield to wells from this aquifer was estimated to be 2,000 gallons per minute. Quaternary alluvium of Pleistocene and Holocene age occurs in most major stream valleys. The aquifer in the Republican River valley yields as much as 2,000 gallons per minute to irrigation wells. Water levels in the Ogallala Formation commonly declined from 5 to 40 feet during 1950-77 as a result of irrigation withdrawals. Recharge from irrigation by stream diversions have raised water levels as much as 25 feet in the Grand Island Formation and as much as 15 feet in the Quaternary alluvium of the Prairie Dog Creek valley. (USGS)

POSITION OF THE SALTWATER-FRESHWATER INTERFACE IN THE UPPER PART OF THE FLORIDAN AQUIFER, SOUTHWEST FLORIDA, 1979,
Geological Survey, Tallahassee, FL. Water Resources Div.
J. D. Fretwell.
USGS Open-File Report 82-90 (WRI), 1982. 1 Sheet, 6 Fig, 1 Tab, 14 Ref.

Descriptors: *Observation wells, *Saline-freshwater interfaces, Aquifers, Monitoring, Groundwater management, Water consumption, Limestone, *Florida, Floridan aquifer.

The position of the saltwater-freshwater transition zone in the Floridan aquifer along coastal southwest Florida is depicted by the 250 milligram per liter line of equal chloride concentration in the upper producing zone of the aquifer. The line was interpolated from chloride concentration data for wells open to the upper producing zone of the aquifer and plotted on a map having a scale of 1:250,000. The line generally lies inland within 5 miles of the coast in areas extending from latitude 29 degrees in Citrus County southward to southern Hillsborough County. In Manatee and Sarasota Counties, the line generally lies with 2 miles of the coast, except in southern Sarasota County where it extends eastward along the Charlotte-DeSoto County line. Knowledge about the position and movement of the 250 milligram per liter line is significant in the effective management of the ground-water resources of coastal areas. The present position of the line will be used as a basis for detecting future movement of the saltwater-freshwater interface. (USGS)

SOURCES OF COMPUTER PROGRAMS IN HYDRAULICS.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 106, No HY5, p 915-922, May, 1980.

Descriptors: *Computer programs, *Mathematical models, *Bibliographies, Publications, Documentation, Hydraulic engineering.

A list is presented of bibliographies and other publications that enumerate mathematical, numerical, and computer models of use to hydraulic engineers. The first part of the list contains sources that are in the form of a formal publication. The second part is composed of ad hoc lists prepared at the request of the Task Committee on Computational Hydraulics or informal lists made for previous projects. Although many computer programs exist, the number of lists and bibliographies is rather small. Thus, the list presented is not exhaustive. (Small-FRC)

COMPILATION OF SELECTED GROUND-WATER-QUALITY DATA FROM THE SAN JOAQUIN VALLEY, CALIFORNIA,
Geological Survey, Sacramento, CA. Water Resources Div.
R. P. Fogelman.
Available from the OFSS, USGS, Box 25425, Fed. Ctr. Denver, CO 80225, Price: $36.25 in paper copy, $3.50 in microfiche.

Descriptors: *California, Groundwater, Water wells, Water analysis, Water chemistry, *Data collections, Water quality, San Joaquin Valley.

The Central Valley of California is one of the most notable structural depressions in the world. It is surrounded by mountains and filled with alluvium derived from those mountains. The San Joaquin Valley is the southern two-thirds of the Central Valley and is bordered on the east by the Sierra Nevada, on the west by the Coast Ranges, on the north by the Sacramento-San Joaquin River Delta area, and on the south by the Tehachapi Mountains. The San Joaquin Valley is probably most noted for its intensive agricultural development, and boasts one of the greatest agricultural economies in the world. The development of ground water has been important to this agricultural boom and subsequently the chemical quality of the ground water is of great interest, especially with respect to maximum agricultural yields as well as domestic uses. This report compiles and summarizes the ground-water-quality data published by the U.S. Geological Survey since about 1950. It includes analyses from more than 5,200 wells. The scope of the study includes the evaluation of the distribution of the water-quality sample by time, aquifer, and area. The distribution is complicated by inconsistencies of sampling with time and area, so time-trend analysis is difficult in most of the area. (USGS)
W84-00604

ANALYSES OF NATIVE WATER, BOTTOM MATERIAL, ELUTRIATE SAMPLES AND DREDGED MATERIAL FROM SELECTED SOUTHERN LOUISIANA WATERWAYS AND SELECTED AREAS IN THE GULF OF MEXICO, 1979-81,
Geological Survey, Baton Rouge, LA. Water Resources Div.
D. L. Lurry.
USGS Open-File Report, 82-690, 1983, 300 p, 11 Fig, 16 Tab, 15 Ref.

Descriptors: *Dredging, *Louisiana, Biochemical oxygen demand, Waste disposal, Effluents, Environmental effects, Nutrients, Pesticides, Trace elements, *Water quality, *Gulf of Mexico, Lower Mississippi River, *Calcasieu River, Mississippi River Gulf Outlet, Intracoastal Waterway, New Orleans to Venice Hurricane Protection Project, *Elutriate.

The U.S. Geological Survey was requested by the U.S. Army Corps of Engineers, New Orleans District, to provide water-quality data to evaluate environmental effects of dredging activities in selected reaches of the Calcasieu River in southwestern Louisiana. Samples were collected from the upper and lower Calcasieu River between January 1980 and March 1981. Thirty-three samples (22 native-water and 11 effluent) were collected from eleven dredging sites. In addition, a series of elutriate studies were conducted between July 1979 and July 1981 to determine water quality as a basis for assessing possible environmental effects of proposed dredging activities in the following areas: Grand Bayou and Martins Canal near Happy Jack, unnamed bayou near Port Sulphur, Grand Bayou and Pipeline Canal near Port Sulphur and Bayou des Plantins near Empire; Mississippi River Gulf Outlet and Inner Harbor Navigation Canal; Southwest Pass; Barataria Bay; Atchafalaya Bay at Eugene Island; Calcasieu Ship Channel. Samples of native water and samples of bottom material were collected from 22 different sites and elutriate (mixtures of native water and bottom material) samples were prepared and analyzed. Four proposed ocean-disposal sites were sampled for bottom material only. Samples were analyzed for selected chemical and biological constituents and physical properties. (USGS)

HYDROLOGY OF AREA 42, WESTERN REGION, INTERIOR COAL PROVINCE, ARKANSAS,
Geological Survey, Little Rock, AR. Water Resources Div.
C. T. Bryant, F. P. Lyford, K. L. Stafford, and D. M. Johnson.
USGS Water Resources Investigations, Open File Report 82-636, Jan. 1983, 87 p, 46 Fig, 13 Tab, 28 Ref.

Descriptors: *Coal mining, *Strip mines, Hydrologic aspects, Water quality, Surface waters, Subsurface waters, *Arkansas, *Interior coal province, Arkansas Valley coal region, *Arkansas River Basin.

This report is one of a series presenting general hydrologic information in selected coal-mining basins and is designed to be useful to mine owners and operators and consulting engineers in the preparation of requests for mining permits. The western region of the Interior Coal province is divided into seven hydrologic assessment reporting areas. This report is for area 42, located at the southern end of the province, in the Interior Highlands of West-Central Arkansas. The U.S. Geological Survey in this area operates (1981) a network of 20 hydrologic data collection stations to monitor the stream flow. Data collected include rate of flow and water quality information. This report presents data from this effort as well as analyses and interpretations of this and other pertinent data descriptive of the hydrology. (USGS)

HYDROLOGIC DATA FOR URBAN STUDIES IN THE AUSTIN, TEXAS, METROPOLITAN AREA, 1981,
Geological Survey, Austin, TX. Water Resources Div.
R. M. Slade, Jr., J. E. Veenhuis, M. E. Dorsey, H. Gardiner, and A. E. Smith.
USGS Open File Report 83-44, 1983, 309 p, 17 Fig, 21 Tab, 10 Ref.

Descriptors: *Rainfall-runoff relationship, Storm runoff, Streamflow, Hydrographs, Mass curves, Hydrologic data, *Data collections, *Urban areas, Water quality, Austin, *Texas, Colorado River(Tex), Balcones Escarpment, Edwards aquifer.

Rainfall and runoff data collected during the 1981 water year for the Austin, Texas metropolitan area are reported. In 1975, the program was expanded to include the collection of water-quality data. In 1978, the program was expanded to include a ground-water resources study of the south Austin metropolitan area in the Balcones Fault Zone. The information will be useful in determining the effect of urbanization on flood peaks, volume, and water quality. The major streams in the study area are Onion Creek, Baron Creek, Walnut Creek, Bull Creek, Boggy Creek, Shoal Creek, Williamson Creek, Slaughter Creek, Bear Creek, and Waller Creek. All streams in the area are within the Colorado River basin. Detailed rainfall-runoff computations are presented for several storms during the 1981 water year. Water-quality data for sites in the Austin metropolitan area are also given in this report. (USGS)
W84-00608

DEVELOPMENT OF GROUND-WATER RESOURCES IN ORANGE COUNTY TEXAS, AND ADJACENT AREAS IN TEXAS AND LOUISIANA, 1971-80,
Geological Survey, Austin, TX. Water Resources Div.
C. W. Bonnet, and R. K. Gabrysch.
USGS Open-File Report 82-330, 1982. 57 p, 11 Fig, 5 Tab, 18 Ref.

Descriptors: *Groundwater, *Aquifers, *Water levels, Drillers logs, Observation wells, Chemical analyses, Saline water encroachment, Chlorides, Pumpage, Land-surface subsidence, Orange County, *Texas, Louisiana.

The major water-bearing unit in the study area is the Chicot aquifer. The Chicot aquifer overlies the Evangeline aquifer. The Evangeline aquifer is undeveloped in Orange County, but is developed at Evadale in Jasper County, Texas, and at Silsbee in Hardin County, Texas. Both aquifers consist of unconsolidated and discontinuous layers of sand and clay that dip toward the Gulf of Mexico. Pumpage in Orange County from the lower unit of the Chicot aquifer averaged 21.2 million gallons per day and pumpage from the upper unit of the Chicot averaged about 2 million gallons per day from 1971-79. Pumpage increased in municipal areas and decreased in industrial areas with little net change in total pumpage during the report period. Most water levels continued to decline in Orange County, generally at a slower rate than before 1971. Water levels tended to stabilize in areas where ground-water withdrawals decreased. In some of the areas water levels rose. Bench-mark elevations determined during 1973 show regional land-surface subsidence from 1918-73, generally attributed to ground-water development, to be less than 0.5 foot. Locally, subsidence due to production of oil, gas, saltwater, or sulphur was about 15 feet at Spindletop Dome, Jefferson County, Texas, and as much as 3 feet (.9 meter) near Port Acres gas field, Jefferson County, Texas. Although saltwater encroachment is evident in parts of southern Orange County, the encroachment is not expected to increase because artesian pressure is unlikely to be decreased further due to stable ground-water pumping and a projected increase in the use of surface water to meet future demands. (USGS)

AVAILABILITY AND QUALITY OF WATER FROM THE DAKOTA AQUIFER, NORTHWEST IOWA,
Geological Survey, Iowa City, IA. Water Resources Div.
M. R. Burkhart.
USGS Open-File Report 82-264, (1982). 118 p, 11 Fig, 5 Tab, 15 Ref.

Descriptors: *Iowa, *Aquifer, *Water quality, Irrigation, Sulfates, Dakota aquifer, *Water availability.

The Dakota aquifer in northwest Iowa consists of sandstones in the Dakota Formation. Sandstone beds are from less than 10 to more than 150 feet thick and cumulatively total more than 200 feet throughout much of the area. The aquifer is confined by shale, carbonate rocks, till and loess. Water flows from the north-central part of the area to the south and southwest. Recharge is through leakage from above. Discharge is to underlying aquifers and alluvium along the Missouri and Big Sioux Rivers. An average hydraulic conductivity of 300 gallons per day per foot squared was used to estimate potential yield to wells. Yields of more than 350 gallons per minute can be commonly expected and more than 1000 gallons per minute can be produced in some areas. The quality of water from the Dakota is a calcium-magnesium-sulfate type which is generally suitable for irrigation. Water quality may be locally altered by leakage from the underlying Paleozoic aquifers if withdrawals reverse the natural flow from the Dakota into the Paleozoic. Such a reversal may exist around the City of LeMars. The presence of radionuclides exceeds recommended limits at several sites. (USGS)

DRAINAGE DIVIDES, MASSACHUSETTS--HUDSON RIVER BASIN, BOSTON, MASSACHUSETTS,
Geological Survey, Boston, MA. Water Resources Div.
S. Wandle, Jr.
USGS Open-File Report 81-1199, 1982. 2 p, 5 Maps.

Descriptors: *Drainage basins, Surface waters, *Massachusetts, *Hydrologic data, *Maps, Data collections, Hudson River, Northern Berkshire County.

Drainage boundaries for selected subbasins in northern Berkshire County, Massachusetts, are delineated on five topographic quadrangle maps at a scale of 1:24,000. Drainage basins are shown for all U.S. Geological Survey data-collection sites and for mouths of major rivers. Drainage basins are shown for the outlets of lakes or ponds and for rivers where the drainage area is greater than 3 square miles. Successive sites are indicated where the intervening area is at least 6 square miles on tributary streams and 10 square miles along the Hoosic or North Branch Noosic Rivers. (USGS)

GROUND-WATER PUMPAGE IN NASSAU COUNTY, LONG ISLAND, NEW YORK, 1920-77, INTRODUCTION AND USER'S GUIDE TO THE DATA COMPILATION,
Geological Survey, Syosset, NY. Water Resources Div.
C. Kilburn.
USGS Open-File Report 81-499, 1982. 25 p, 2 Maps, 2 Tab, 1 Ref.

Descriptors: *Groundwater, *Withdrawal, *Well data, *New York, Nassau County, Long Island, *Ground-water pumpage.

Pumpage data from about 2,100 wells used for public and nonpublic water-supply in Nassau County from 1920-77 have been collected and are available for public inspection at the U.S. Geological Survey office in Syosset, Nassau County. Except for wells in use before 1920, these data constitute the entire record available through 1977. The data are divided into two categories--pumpage from wells used for public supply, and pumpage from wells used mainly for industrial and commercial uses, designated as nonpublic water supply. Pumpage is tabulated by well or well field and is given by month or year with an annual total. The report serves as an introduction and user's manual to the data, which are available for inspection but are not included in the report because they fill several hundred pages. The report describes the method of reporting pumpage on Long Island and how pumpage values were derived from records. It also includes well-completion data two maps showing the location of all (USGS)

criptors: *Water quality, *Lignite, *Mining, d use, *Mississippi, Oktibbeha County, Choc- County, Noxubee County, Winston County.

water-quality sampling program was initiated in 0 to determine background hydrologic data in ential lignite mining areas of Mississippi. This ort is the third in a planned five-part series to vide data to assess future impacts of mining on ll streams. The data indicates that most streams he study area have a dissolved-solids concentra- n less than 100 mg/. The major ion concentra- ns were generally less than 10 mg/. Concentra- ns of arsenic, cadmium, mercury, and selenium in bottom material samples were below detectable limits. Cobalt, lead, zinc, copper, and chromium concentrations exceeded 10 micro-/g at all sites and maganese exceeded 1000 micro-/g at five sites. (USGS)

FLOODS FROM SMALL DRAINAGE AREAS IN ALASKA,
Geological Survey, Anchorage, AK. Water Resources Div.
S. H. Jones.
USGS Open-File Report 83-258, 1983. 54 p, 22 Fig, 5 Tab, 17 Ref.

Descriptors: Floods, Flood characteristics, *Flood hydrographs, *Flood peaks, Flood frequency, *Drainage areas, *Data collections, *Alaska, Crest-stage gages.

Flood peak-stage and associated discharge data collected since 1963 in small (generally less than 100 square miles) drainage areas in Alaska are presented in tabular and graphical form. The report also contains table of computed magnitudes of floods at selected recurrence intervals (2, 5, 10, 25, and 50 years) for sites having 10 or more years of record. Data have been collected at approximately 125 sites since the 'small-streams program' began in 1963; 64 crest-stage gages and 3 continuous recording gages are being operated in 1983. (USGS)

WATER RESOURCES DATA--VIRGINIA, WATER YEAR 1982,
Geological Survey, Richmond, VA. Water Resources Div.
B. J. Prugh, Jr, F. J. Easton, and D. D. Lynch.
Available from the National Technical Information Service, Springfield, VA 22161 as PB83-103192, Price codes: A21 in paper copy, A01 in microfiche. USGS Water Data Report VA-82-1, 1983. 460 p, 6 Fig, 3 Tab. Prepared in cooperation with the State of Virginia and with other agencies.

Descriptors: *Virginia, *Hydrologic data, *Surface water, *Groundwater, *Water quality, Flow rate, Gaging stations, Lakes, Reservoirs, Chemical analyses, Sediments, Water temperatures, Sampling sites, Water levels, Water analyses, *Data collections.

Water resources data for the 1982 water year for Virginia consist of records of stage, discharge, and water quality of streams; stage, contents, and water quality of lakes and reservoirs; and water levels and water quality of ground-water wells. This volume contains records for water discharge at 200 gaging stations; stage only at 1 gaging station; stage and contents at 10 lakes and reservoirs; water quality at 32 gaging stations and 8 wells; and water levels at 59 observation wells. Also included are data for 73 crest-stage partial-record stations. Locations of these sites are shown. Additional water data were collected at various sites not involved in the systematic data-collection program. Discharge measurements were made at 41 coal-monitoring partial-record stations and at 199 low-flow partial-record station. Miscellaneous data were collected at 119 measuring sites and 94 water-quality sampling sites. (USGS)

HYDROGEOLOGY OF SIGNIFICANT SAND AND GRAVEL AQUIFERS - NORTHERN YORK AND SOUTHERN CUMBERLAND COUNTIES, MAINE,
Geological Survey, Boise, ID. Water Resources Div.
A. L. Tolman, D. H. Tepper, G. C. Prescott, Jr., and S. O. Gammon.
USGS Open-File Report 83-1, 1983. 4 Maps, 30 Ref.

Descriptors: *Areal hydrogeology, *Glacial aquifers, *Glacial sediments, *Water quality, *Groundwater pollution, Groundwater availability, Well yield, Seismology, Resistivity, Water pollution sources, Water table fluctuations, *Maps, *Maine, Northern York County, Southern Cumberland County.

This reconnaissance-level hydrogeologic study covers an area of 875 square miles in northern York and southern Cumberland Counties, Maine. This region contains the densest concentration of both aquifers and population in the State, and was selected for study in preparation for management and protection programs being developed at the State and Federal level. This map report includes: identification and mapping of boundaries of approximately 172 square miles of significant aquifers; estimated aquifer yields; depth to water table; depth to bedrock/thickness of unconsolidated deposits; bedrock surface topography; stratigraphy and stratigraphic relationships; characterization of regional ground-water chemistry; and assessments of the effects of 37 potential contamination sites on ground-water quality. The aquifers within the study area are typically less than 50 feet thick, become finer-grained with depth, and are underlain by marine deposits or till. About 10 square miles of the aquifers studied can sustain well yields of more than 50 gallons per minute but few of these aquifers are capable of yielding quantities sufficient for industrial or municipal water supplies. The regional ground-water, based on samples from 23 wells, has the following chemical characteristics: it is slightly acidic to neutral; has less than 100 milligrams per liter of dissolved solids; sodium, calcium, and magnesium are the dominant cations; bicarbonate is the solids; sodium, calciu
magnesium are the dominant cations; bica
is the dominant anion; and the water is so
regional ground-water quality is excellent b
centrations of iron and manganese are high
in some localities to limit the practical use
water without treatment. Although none o
ground-water contamination sites investiga
a severe impact on ground-water quality,
mulative impacts of these sites may have
significance. (USGS)

peration of multipurpose reservoirs in se-
central Arizona requires timely and depend-
reamflow and snowmelt information. Since
onventional ground surveys and aerial ob-
ons have been used in an attempt to monitor
changing moisture conditions in the Salt-
watershed. Since 1974, repetitive satellite
over observations have greatly reduced the
ty for frequent routine aerial snow-recon-
ce flights over the mountains. Although
types of satellite imagery can provide the
c coverage necessary to map the large
overed areas in the 34,000-square-kilometer
ned, frequent repetitive coverage is required
itor the rapid changes in snow cover. High-
on (80 meter) multi-spectral imagery pro-
by the Landsat satellite series enabled rapid
curate mapping of snow-cover distributions
ll- to medium-sized subwatersheds; howev-
dsat imagery provided only one observation
9 days of about a third of the watershed.
esolution 1 kilometer) imagery acquired by
OS and SMS/GOES meteorological satellite
provides the daily synoptic observation nec-
to monitor the rapid changes in snow-cov-
ea in the entire watershed. A comparison of
overed area measurements and correspond-
an daily runoff rates indicates that short-
unoff volumes can be predicted from daily
tial satellite snow-cover observations. Sea-
runoff predictions have been improved by
a modified hydrometeorological model.

POTENTIOMETRIC SURFACE OF THE FLORIDAN AQUIFER IN THE ST. JOHNS RIVER WATER MANAGEMENT DISTRICT AND VICINITY, FLORIDA, SEPTEMBER 1982,
Geological Survey, Tallahassee, FL. Water Resources Div.
G. R. Schiner, and E. C. Hayes.
Available from the OFSS, USGS, Lakewood, CO 80225, Paper copy $3.50; Microfiche $1.00. USGS Open-File Report 83-30, 1983. 1 p, 1 Fig.

Descriptors: *Potentiometric level, *Groundwater, Hydrologic aspects, *Aquifer, Hydrogeology, *Maps, *Florida, St. Johns River Water Management District.

This map presents the potentiometric surface of the Floridan aquifer in the St. Johns River Water Management District and vicinity for September 1982. The Floridan aquifer is the principal source of potable water in the area. Water-level measurements were made on approximately 1,000 wells and on several springs. The potentiometric surface is shown mostly by 5-foot contour intervals. In the Fernandina Beach area a 40-foot interval is used to show a deep cone of depression. The potentiometric surface ranged from 131 feet above NGVD (National Geodetic Vertical Datum of 1929) in Polk County to 68 feet below NGVD in Nassau County. Water levels continued to recover from record low levels set in September 1981. Except in a few places, water levels throughout the District rose above September 1981 levels. September 1982 levels were as much as 10 feet and commonly 2 to 3 feet higher than the below normal September 1981 levels. (USGS)

SUPPLEMENT TO THE NEW MEXICO THREE-DIMENSIONAL MODEL (SUPPLEMENT TO OPEN-FILE REPORT 80-421),

Geological Survey, Albuquerque, NM. Water Resources Div.
G. A. Hearne.
USGS Open-File Report 82-857, 1982. 163 p, 5 Fig, 8 Tab, 5 Ref.

Descriptors: *Computer programs, *Documentation, *Computer models, Data processing, Groundwater, Leakage, Water table, Aquifer, Aquicludes, River, *New Mexico.

The computer program documented in Open-File Report 80-421 has continued to evolve in response to needs. By January 1981, changes included the following: (1) treatment of head-dependent boundaries and specified-flow boundaries and (2) code which executes on the CRAY-1 computer. This report provides instructions for compiling and executing the computer program on the CRAY-1 at Kirtland Air Force Base. (USGS)

SELECTED HYDROLOGIC DATA FOR NORTHERN UTAH VALLEY, UTAH, 1935-82,
Geological Survey, Salt Lake City, UT. Water Resources Div.
L. Appel, D. W. Clark, and P. E. Fairbanks.
USGS Open-File Report 82-1023, 1982. 94 p, 2 Fig, 8 Tab, 4 Ref.

Descriptors: Water resources, *Utah, *Groundwater, Surface water, *Water quality, Discharge, *Water levels, Water-resources data, Lehi, Provo, Orem, Utah Valley, Utah County, *Utah.

Presented are hydrologic data collected in northern Utah Valley from 1935 to 1982. The data include records of selected wells, springs, drains, irrigation ditches, streams, water quality, and drillers' logs of selected wells. Some of the data were previously published by the Geological Survey and cooperating agencies. (USGS)

HYDROPOWER IN PORTUGAL: PROSPECTS FOR LARGE RESERVOIRS,
Coimbra Univ. (Portugal).
J. L. Serafim.
International Water Power and Dam Construction, Vol 35, No 2, p 40-42, February, 1983. 3 Fig, 2 Tab.

Descriptors: *Water resources development, *Reservoirs, Portugal, Rivers, Hydroelectric power, Design criteria, Cost anlysis, Economic aspects.

Areas and rivers in the country of Portugal where the most cost effective development of hydropower is likely to take place are described. The waters of rivers coming from Spain constitute a very appreciable hydraulic resource. In addition, good reservoirs and dam sites exist in paleozoic and granitic rocks, providing substantial hydroelectric resources to Portugal. The irregularities of rain and flow from the north to the south of the country, and from winter to summer and from year to year, make it appropriate to construct large reservoirs, high dams and powerful plants. The overall theoretical hydroelectric potential of the country for a year of average precipitation has been estimated as 32000 GWh, of which only about 30% is being exploited. Installed capacity is around 2300 MW in 25 large hydro plants of over 10 MW capacity. To obtain such a large amount of power, in a country of 89000 sq km area it will be necessary to build about 46 new large powerplants and dams, to increase substantially the installed capacity in at least 10 existing plants and to use around 80 small-scale systems, either existing or new, of less than 10 MW capacity. At present, because of the lack of funds, difficulties in buying inundated land, delays in international agreements and other reasons, there are only two hydropower stations under construction. PINPOINTING PIPE RUPTURES,
Compagnie Generale des Eaux, Paris (France).
A. Divenot.
Water/Engineering and Management, Vol 129, No 12, p 36-37, 1982. 4 Fig.

Descriptors: *Pipelines, *Rupturing, *Computers, Mechanical failure, Automation, Monitoring, Mathematical equations.

A method based on the use of a mathematical network model has been developed to locate ruptures in water distribution pipes quickly and accurately. It has two advantages over the established trial and error process. Not only do the automatic measurements preclude any need for human intervention, they also provide results of better quality, as they make a universal search instead of calculated point-by-point searches. Of the various data stored in a typical distribution system control computer, the most relevant are the flow rates at the supply sources and the pressures measured at the sources and in the system. The cumulative total of these flow rates is equal to the network's instantaneous consumption. Unfortunately, every process based on knowledge of the flow from a break indicated by variation of the source flows has the serious drawback of not being applicable when one of the flowrate sensors is unavailable for one reason or another. But if the search is based on pressure sensors, shutting down one or even several of them does not make the system inoperable. (Baker-FRC)

RECOMMENDED STANDARDS FOR WATER WORKS.
New York State Health Department Bulletin 42, Health Education Service, Albany, NY, 1982. 88 p, 1 Fig, 1 Tab.

Descriptors: *Standards, *Guidelines, *Design standards, *Specifications, *Water supply systems, *Engineering, Water supply development, Water storage, Pumping plants, Chemical treatment, Distribution.

These standards are intended to serve as 1) a guide in the design and preparation of plans and specifications for public water supply systems, 2) to suggest limiting values for items upon which an evaluation of such plans and specifications may be made by a reviewing authority, and 3) to establish, as far as practicable, uniformity of practice. The standards given are for submission of plans, general design considerations, pumping facilities, finished water storage and distribution systems. In addition, the manual contains policy statements on: 1) Package water treatment plants for public water supplies, 2) organic removal treatment for public water supplies, 3) ozonation for public water supplies, 4) distribution system corrosion control for public water supplies, and 5) salt storage for highway use and public water supplies. (Garrison-Omniplan)

HIGH WOOD RESERVOIR--PLANNING, DESIGN AND CONSTRUCTION,
N. C. Pasley.
Water Services, Vol 87, No 1043, p 11-12, 15-16, 18, January, 1983. 4 Fig, 2 Tab.

Descriptors: *Reservoir construction, *Soil properties, *Concrete, Water storage, Reservoir design, Design criteria, Construction, High Wood Reservoir, Excavation, *United Kingdom.

The planning, design, and construction of the High Wood Reservoir, upstream of the River Itchen, United Kingdom, is described. The 135 m liter concrete storage reservoir was built to protect the treatment works influent against gross river pollution, provide a 2 days' supply, and smooth out variations in river water quality. The foundation soil was cohesive, inorganic, and medium to highly plastic, with low coefficients of compressibility and volume change. A 600 m long, 5 m deep perimeter drain was used to dewater the site and to control the groundwater level, which was near the surface. Two grades of concrete were specified, one for the mass concrete and blinding c and the other for reinforced concrete. A 65,000 cu m of soil was excavated and inco ed into the reservoir banks. COMMODITY PIPELINES MAY AID W DEVELOPMENT.
World Water, Vol 5, No 12, p 38-39, 41, D ber, 1982. 1 Tab.

Descriptors: *Pipelines, *Water transport, * oping countries, Transportation, Water c ance, Conduits, Slurries, Aquatrain.

The Aquatrain is a method of commodity p transport being tested by the W. R. Grace C ny. It proposes to move coal packaged in duty plastic bags and carried by high p water flow through a 1 m pipeline from m Colorado to California. Fresh water for th leg of the transport would come from the River in the Rockies. At Rifle the Yampa would be used for municipal supplies or discl into the Colorado River. Water for the rem of the line would be obtained from a saline C do tributary and be discharged, after recov the coal bags, into the Pacific. Other develo in pipeline transport include a more viscous to help keep larger particles in suspensio movement of agricultural products, such as pods. In developing countries poor roads an of railroads make the pipeline alternative tive. Commercial slurry pipelines of lengths 439 km currently move coal, limestone, ore other mineral products in the U.S. and man eign countries. (Cassar-FRC)

8B. Hydraulics

MAINTAINING TIDAL INLET CHANNEL FLUIDIZATION,
Lehigh Univ., Bethlehem, PA. Dept. of Civ gineering.
R. N. Weisman, A. G. Collins, and J. M. Park
Journal of the Waterway, Port, Coastal and O Division, Proceedings of the American Soci Civil Engineers, Vol 108, No WW4, p 52 November, 1982. 9 Fig, 11 Ref.

Descriptors: *Fluidization, *Channel imp ment, *Sediment control, Sand, Tidal hydra Navigation canals, Corson Inlet, *New J Pipes, Inlets.

A navigable tidal inlet channel was stabilized fluidization technique, an alternative to ch dredging. Laboratory and field studies were on a process using pipes with small holes dril frequent uniform intervals, placed in the ebb channel at a navigable depth. Water is pumpe the pipe to fluidize the sand above the pipe, is then removed by pumping, flowing do gradient, or sweeping out to sea with the ebb For sand of 0.4 mm diameter, laboratory st established a fluidization hole size of 0.31 hole spacing of 5.08 cm, and a pipe flow rate liters per sec per m of pipe (greater for diameter sands), pipe diameter of 15.2 cm, length of 12.2 m, and separation of parallel pi 1.83 m. Field tests run at Corson Inlet, Jersey, showed that the full-scale system s have a pipe spacing of 3 m with sequential p ing through pairs of parallel pipes. Problem countered were clogging of the holes with sucking of sand into the pipe, and armoring ar the pipes with clam shells. (Cassar-FRC)

URING SWIRL IN PUMP MODEL IES,
ang.
Water, Vol 5, No 12, p 42-43, December, 4 Fig.

iptors: *Pumps, *Flow pattern, *Rotational Hydraulic machinery, Impellers, Model studortices, Flow velocity.

Pump intake model studies are generally conducted with a geometrically-scaled suction pipe or siphon pipe without including a model rotation pump impeller. This assumes that the impeller has no upstream effect on the flow by adding to the approach swirl or increasng vortex activity and does not produce any prerotation. Experiments revealed that the impeller produces no prerotation from the design flow to 1.5 times the design flow. However, if pumps are to be operated at flows less than 50% of design flow, the impeller must be modeled. (Cassar-FRC)
W84-00566

PIPELINE CLEANING AND MAINTENANCE - NEW EQUIPMENT, NEW IDEAS,
R. W. Edwards.
Water Services, Vol 84, No 1013, p 418-423, July, 1980.

Descriptors: *Sewer systems, *Pipelines, *Maintenance, Cleaning, Water mains, Conveyance structures.

Technological innovations in servicing sewers and pipelines are summarized. A dual-purpose vehicle for cleaning sewers has dispensed with the separate suction unit and saves capital, operational, and maintenance costs. One crew can carry out high-pressure jetting and suction removal of deposited silt. One such unit is equipped with a jetting control panel, gauges for vacuum and air pressure, and indicators for water, sludge, and hydraulic-oil levels. This unit is built on a 16 ton chassis with a diesel engine and five speed gear box. A new relining process for water mains is the use of epoxy resin rather than the well-established practice of bitumen relining. The resin possesses many desirable features for pipes up to 30 mm in diameter. It has an estimated life of 30 years and can be applied cheaply. A major advantage of the new process is its speed. Another innovation is the use of flexible pigs for cleaning trunk mains. On a short trial run, a pig designed for 812 mm to 914 mm diameter pipes operated successfully with a pressure head of less than 1.8 m to set it in motion. (Small-FRC)
W84-00589

EFFICIENCY PERFORMANCE CRITERIA FOR IRRIGATION SYSTEMS,
Oregon State Univ., Corvallis. Dept. of Agricultural Engineering.
H. J. Hansen, and M. N. Shearer.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-132455, Price codes: A04 in paper copy, A01 in microfiche. Water Resources Research Institute Publication WRRI-90, Oregon State Univ., Corvallis, November 1983. 82 p, 5 Fig, 7 Tab, 22 Ref, 13 Append. OWRT B-070-ORE(1), 14-34-0001-9157.

Descriptors: *Pump testing, *Pumping plants, *Pumps, Irrigation, Irrigation efficiency, Irrigation engineering, *Irrigation operation, Irrigation practices, *Oregon.

The efficiency performance levels of existing irrigation pumping plant systems in Oregon were determined from tests of selected systems under field operation conditions. Usable test data were obtained from 529 units out of 545 tested. The overall plant efficiency ranged from 14 to 79 percent. Twenty-eight percent of the centrifugal and 34 percent of the turbine pumping plant systems had efficiencies of 65 percent or greater. Twenty percent of the centrifugal and 23percent of the turbine units were operating under 50% efficiency. A 65% overall plant efficiency is generally considered achievable. Units under 50% efficiency generally warrant consideration for repair or replacement. The two primary causes of low overall plant efficiencies were (a) improperly designed or sized fittings around pumps (only 38% were rated satisfactory) and (b) mismatches of pump and sprinkler systems. Very often, laterals had been added, deleted or changed without making pump adjustments. Pump efficiencies ranged from 24% to 87% with 68% operating above 60% efficiency. Comparing individual pump performance with the specific manufacturer's pump curve revealed that 55% of the pumps were operating within 4% of their respective curves -- a very acceptable performance range.

HOW TO MAINTAIN PVC SEWER PIPE,
W. D. Nesbeitt.
Water and Pollution Control, Vol 118, No 10, p 22-25, October, 1980. 2 Fig

Descriptors: *Plastic pipes, *Maintenance costs, *Sewerage, Pipelines, Hydraulic structures, Sanitary engineering, Maintenance, Corrosion.

A review of the maintenance requirements for polyvinyl chloride (PVC) sewer pipe manufactured to meet ASTM D3034(DR35) standards is presented. The PVC sewer pipe's response to aggressive environments commonly found in gravity-flow sanitary sewer systems is evaluated, and some cost-effective maintenance procedures for PVC sewer systems are recommended. The most commonly experienced aggressive environment problems of sanitary sewer systems include root intrusion, infiltration, excessive slime accumulation, grease deposition, grit accumulation and corrosion. Tests conducted to evaluate the integrity of PVC sewer pipe gasket joints in situations of excessive deflection caused by severe earth loading showed that PVC piping with properly installed gaskets was not subject to root intrusion problems. Similarly, slime accumulation and infiltration occurred relatively infrequently in PVC sanitary sewer pipes. The greatest concern with slime accumulation is the production of sulfuric acid, which often causes pipe corrosion. PVC pipe was not usually subject to sulfuric acid corrosion. Methods of slime and grease removal by mechanical blockage removal equipment showed only slight damage, in some cases, to PVC pipes. PVC pipe is also highly resistant to abrasion in gravity systems, low in maintenance costs, and easy to install. A maintenance schedule of periodic inspection, visually or by television, and periodic preventive measures such as 'ball', rod, 'pig', or high pressure cleaning are recommended. (Geiger-FRC)

THE ECONOMICS OF LEAK DETECTION AND REPAIR - A CASE STUDY,
Massachusetts Univ., Amherst. Dept. of Civil Engineering.
E. E. Moyer, J. W. Male, I. C. Moore, and J. G. Hock.
Journal of the American Water Works Association, Vol 75, No 1, p 29-34, January, 1983. 2 Fig, 7 Tab, 13 Ref.

Descriptors: *Leakage, *Economic aspects, *Pipelines, *Maintenance costs, *Case studies, *Cost-benefit analysis, Water loss, Water conveyance, Pipes, Water mains, Maintenance, Water conservation.

A case study of the Westchester Joint Water Works (WJWW) in Mamaroneck, New York, is presented to demonstrate the favorable economics of systematic leak detection and repair of a water distribution system and to offer some insights into leak characteristics and the accuracy of sonic leak detection. Records of surveyors at the time of leak detection, repair crew reports and general records of water usage, costs, and unaccounted for water were reviewed in order to calculate costs and benefits in each year of leak detection. Simple statistical analysis showed that leakage stopped by WJWW saved a net amount of $239,052 over a six-year period. Leaks were classified into six categories and the net economic benefit or loss of repairing each type of leak was estimated. The accuracy of sonic leak detection in determining leak size and

location were obtained by statistically comparing survey and repair reports and the actual location of the leak with that predicted by the survey. On the whole actual and predicted leak locations correlated closely. Other possible tangible and intangible benefits of leak detection and repair include decreased damage to property, lesser loads on treatment facilities, lower total repair costs, decreased total demand, reduced risk of contamination, water conservation and decreased expenditures on leak related expenses. (Geiger-FRC)
W84-00582

CEMENT-BASED SEALS FOR THERMOPLASTIC WATER WELL CASINGS,
Kansas Univ., Lawrence. Dept. of Civil Engineering.
C. E. Kurt.
Water Well Journal, Vol 37, No 1, p 38-40, 1983. 2 Fig.

Descriptors: *Well casings, *Cement, *Construction, *Thermoplastics, Seals, Grout, Wells, Casings, Well water, Well seepage, Well regulations.

Cement-based grouts have been used to seal the annulus between the well casing and the native formation. The placement of this seal is crucial. A grout seal may be required along the entire length of the casing. In other applications only the top 10 or 20 feet of the well casing must be grouted. The purpose of these requirements is to minimize the amount of surface water that can travel through the casing annulus. When it is important that the water from one aquifer not be permitted to flow into another aquifer, only sections of the annulus need to be grouted along the length of casing. When using thermoplastic materials for water well casings the seal provides another very important function. While thermoplastic water well casings have a long history of excellent service in the water well industry it is important to know that they are not as strong as steel casings. For any casing system there are several potential paths for water and contaminants to follow in the annulus along the casing. One path is through the grout material itself. If the best materials are improperly installed a highly permeable seal can result. The property used to measure the flow of fluid through a porous material such as a grout seal is called the coefficient of permeability. It measures the amount of fluid passing through a porous media per unit cross sectional area in a period of time when subjected to a pressure head. A direct approach to demonstrate a good seal is to pressure test the casing. (Baker-FRC)
W84-00586

CORROSION PROTECTION OF CONCRETE AND STEEL TANKS AND RESERVOIRS.
Water Services, Vol 84, No 1010, p 238, 241, April, 1980.

Descriptors: *Protective coatings, *Concrete technology, *Corrosion control, Coatings, Steel, Storage tanks, Wastewater treatment facilities, Reservoirs, Potable water, Epoxy resins.

The useful life of concrete and steel water storage tanks and reservoirs can be prolonged with effective corrosion protection. Sewage handling structures are increasingly exposed to higher temperatures and modern detergents, which increase the power of the sewage to penetrate the concrete surface. Many coatings (epoxy, chlorinated rubber, and coal tar pitch-epoxy) are available for these applications and must be specified according to conditions encountered. Best results are obtained when coatings are applied to properly cleaned surfaces, using the specific method for the material involved. Engineers should use only specialized, experienced contractors who have detailed knowledge of coatings application. It is helpful if these coating specialists are consulted during the planning stage. AQUACULTURE TECHNIQUES: PRELIMINARY STUDIES ON CARRYING CAPACITIES AND CENSUS-TAKING IN SERIAL REUSE PONDS,
Idaho Univ., Moscow. Coll. of Forestry, Wildlife and Range Sciences.
G. W. Klontz, C. M. Herr, and T. J. McArthur.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-120823, Price codes: A04 in paper copy, A01 in microfiche. Idaho Water and Energy Resources Research Institute Completion Report, Moscow, July 1983. 45 p, 5 Fig, 10 Tab, 18 Ref. OWRT A-075-IDA(1), 14-34-0001-2114.

Descriptors: *Oxygen consumption, *Aquaculture, *Rainbow trout, *Pond census-taking, Model studies, *Carrying capacity, Dissolved oxygen, Flow rates, Water temperature, Fish size.

A fish size and water temerature compensated model to measure the oxygen consumption of rainbow trout was developed and tested under laboratory and limited field conditions. The model is log mg/hr 0 sub 2 consumption = 0.847532 + 0.8428 log g/fish + 0.03733C. Although the model is logically and mathematically correct, several technical inaccuracies were detected when the model was applied to determine the number of rainbow trout in a raceway population. These inaccuracies were attributed to the sensitivities of the methods used to determine the dissolved oxygen concentrations and flow rates of the water entering and leaving the systems. Further studies are planned.

Summary Report on Drought Planning by Community Water Systems.
W84-00500 3D

Developing and Monitoring Municipal Groundwater Supplies in Florida,
W84-00573 6D

Projected Demands and Supplies of Water Under Alternative Energy and Agricultural Development Scenarios in the Green River Drainage of Wyoming,
W84-00634 6B

Asbestos in Water Supplies of the Northern New Jersey Area: Source, Concentration, Mineralogy, and Size Distribution,
W84-00683 5B

WATER SUPPLY DEVELOPMENT

Discussion 'Municipal Water Supply Restrictions as Urban Growth Constraints,' by W. B. Lord,
W84-00414 6D

WATER SUPPLY SYSTEMS

Recommended Standards for Water Works.
W84-00501 8A

WATER TABLE

Configuration of the Water Table, March 1980, in the Snake River Plain Regional Aquifer System, Idaho and Eastern Oregon,
W84-00651 7C

Altitude and Configuration of the Predevelopment Water Table in the High Plains Regional Aquifer, Northwestern Oklahoma,
W84-00672 7C

Altitude and Configuration of the 1980 Water Table in the High Plains Regional Aquifer, Northwestern Oklahoma,
W84-00674 7C

WATER TABLE PROFILES

Flow Toward Storage Tunnels Beneath a Water Table 1. Two-Dimensional Flow,
W84-00396 2F

WATER TRANSPORT

Commodity Pipelines May Aid Water Development.
W84-00565 8A

WATER TREATMENT

Clinoptilolite in Drinking Water Treatment for NH4+ Removal (Utilisation De La Clinoptilolite En Potabilisation Des Eaux--Elimination De L'Ion NH4+),
W84-00520 5F

Efficiency of Point-of-Use Treatment Devices,
W84-00569 5F

Discussion of: Role of Adsorption in Biological Extended Activated Carbon Columns, and Author's Response,
W84-00570 5D

Disinfection, Water Quality Control, and Safety Practices of the Water Utility Industry in 1978 in the United States,
W84-00572 5F

Survival of Some Faecal Indicator Bacteria in Drinking Water,
W84-00583 5F

WATER TREATMENT FACILITIES

Proving the Point for Dissolved Air Flotation in Potable Water Plant.
W84-00561 5F

WATER TREATMENT INDUSTRY

Safety and the Human Factor,
W84-00486 5F

WATER WELLS

Water Resources of the Zuni Tribal Lands, McKinley and Cibola Counties, New Mexico,
W84-00646 2F

WATERCRESS

The Dynamics of Growth, the Effects of Changing Area and Nitrate Uptake by Watercress Nasturtium Officinale R. Br. in a New Zealand Stream,
W84-00354 5G

WATERSHED MANAGEMENT

Significance of Eutrophication in Water Supply Reservoirs,
W84-00571 5C

WELL CASINGS

Cement-Based Seals for Thermoplastic Water Well Casings,
W84-00586 8G

WELL DATA

Ground-Water Pumpage in Nassau County, Long Island, New York, 1920-77, Introduction and User's Guide to the Data Compilation,
W84-00614 7C

WELLS
Developing and Monitoring Municipal Groundwater Supplies in Florida,
W84-00573 6D

WEST VIRGINIA
Effects of Underground Mining and Mine Collapse on the Hydrology of Selected Basins in West Virginia,
W84-00547 2F

WETLANDS
Evaluation of High and Prolonged Levels of Sewage Wastewater on Marsh Vegetation,
W84-00494 5C

WHEY
Production of Whey Protein Concentrates with High Solids Content,
W84-00697 3A

WIPED FILM. DISTILLATION
Wiped-Film Rotating-Disk Evaporator for Water Reuse,
W84-00438 3A

WISCONSIN
Low-Flow Characteristics of Streams in the Lake Michigan Basin, Wisconsin,
W84-00546 2E

WITHDRAWAL
Ground-Water Pumpage in Nassau County, Long Island, New York, 1920-77, Introduction and User's Guide to the Data Compilation,
W84-00614 7C

WYOMING
Projected Demands and Supplies of Water Under Alternative Energy and Agricultural Development Scenarios in the Green River Drainage of Wyoming,
W84-00634 6B

Fault Severing of Aquifers and Other Geologically Controlled Permeability Contrasts in the Basin-Mountain Interface, and the Implications for Ground Water Recharge to and Development from the Major Artesian Basins of Wyoming,
W84-00636 2F

Design Rainfall Distributions for the State of Wyoming,
W84-00638 2A

Acid Precipitation in Southeastern Wyoming,
W84-00639 2K

ZERO DISCHARGE
Reusing Cooling Water in an Electric Power Plant,
W84-00386 3E

ZOOPLANKTON
Impact of Changing Acidity on the Trophic Dynamics of Pine Barrens Plankton Communities,
W84-00684 5C

ZUNI INDIAN RESERVATION
Water Resources of the Zuni Tribal Lands, McKinley and Cibola Counties, New Mexico,
W84-00646 2F

AUTHOR INDEX

SELECTED WATER RESOURCES ABSTRACTS

VOLUME 17, NUMBER 3
MARCH 1984

01 -- W84-01050
SWR ABW

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 421, Reston, VA 22092, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are:
Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 17, NUMBER 3
MARCH 1984

W84-00701 -- W84-01050

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Office of Management ond Budget through September 30, 1985.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientitsts, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

Descriptors: *Hydrologic model, *Hydrologic systems, Groundwater quality, Groundwater, Aquifers, Geologic units, *Minnesota, Twin Cities, *Mississippi River, Minnesota River, St. Croix River.

A preliminary quasi-three-dimensional finite-difference ground-water-flow model of the seven-county Twin Cities Metropolitan area was constructed and used to evaluate parameter sensitivity and adequacy of available data. Fourteen geologic units that underlie the study area were grouped into nine hydrogeologic units and were incorporated into a five-layer model. The layers in the simulation model include the Mount Simon-Hinckley, Ironton-Galesville, Prairie du Chien-Jordan, and St. Peter aquifers and the drift. Sensitivity analyses were made for 19 parameter and boundary-condition specifications. Model results are most sensitive to recharge and withdrawal rates and hydrogeologic variations related to drift-filled bedrock valleys. Analyses of available data and results of steady-state simulations indicate that critical data needs for improving the simulation model include (1) spatial and temporal variations in ground-water withdrawals and potentiometric levels, and (2) hydraulic properties of the drift that fills or partly fills bedrock valleys. Areal distribution of calcium, sodium, sulfate, and chloride concentrations were analyzed to provide information on the hydrologic and geochemical relationships between aquifers. Ground water is generally of the calcium magnesium bicarbonate type. Concentration of dissolved solids in the Jordan Sandstone and Mount Simon-Hinckley aquifer generally decreases from southwest to northeast across the study area. This decrease probably reflects differences in the quality of recharge water and geochemical processes within the aquifers such as ion-exchange. (USGS)

GRAVITY SURVEY OF DIXIE VALLEY, WEST-CENTRAL NEVADA,
Geological Survey, Boise, ID. Water Resources Div.
D. H. Schaefer.
USGS Open-File Report 82-111, 1983. 17 p, 6 Fig, 2 Tab, 16 Ref.

Descriptors: *Gravimetric prospecting, Geophysical prospecting, Dixie Valley, *Nevada, *Alluvial thickness, Geothermal resources.

Dixie Valley, a northeast-trending structural trough typical of valleys in the Basin and Range Province, is filled with a maximum of about 10,000 feet of alluvial and lacustrine deposits, as estimated from residual-gravity measurements obtained in this study. On the basis of gravity measurements at 300 stations on nine east-west profiles, the gravity residuals reach a maximum of 30 milligals near the south-central part of the valley. Results from a three-dimensional inversion model indicate that the central depression of the valley is offset to the west of the geographic axis. This offset is probably due to major faulting along the west side of the valley adjacent to the Stillwater Range. Comparison of depths to bedrock obtained during this study and depths obtained from a previous seismic-refraction study indicates a reasonably good correlation. A heterogeneous distribution of densities within the valley-fill deposits would account for differing depths determined by the two methods. (USGS)

EVALUATION OF WATER-QUALITY CHARACTERISTICS OF PART OF THE SPOKANE AQUIFER, WASHINGTON AND IDAHO, USING A SOLUTE-TRANSPORT DIGITAL MODEL,
Geological Survey, Tacoma, WA. Water Resources Div.
J. J. Vaccaro, and E. L. Bolke.
USGS Water-Resources Investigations Open-File Report 82-769, 1983. 69 p, 26 Fig, 7 Tab, 23 Ref.

Descriptors: Mathematical model, *Groundwater, *Water quality, Chlorides, *Surface/groundwater relationships, Spokane Valley, Spokane River, *Washington, *Idaho.

A digital model was developed and used to simulate solute transport of conservative ions in the Spokane aquifer. The model calculates a solute-flux budget that can be used for management purposes. The model was used specifically to estimate the impact of the chloride ion from septic-tank recharge and from land-surface-applied water on the water quality of the Spokane aquifer. Model analysis showed the estimated impact on the aquifer from these sources to be less than a 1-mg/L increase over about 80% of the aquifer, and about 3 mg/L in some peripheral locations. Other water-quality-management schemes using various man-made or natural stresses can be tested with the model. (USGS)

GEOTHERMAL RESOURCES OF THE WESTERN ARM OF THE BLACK ROCK DESERT, NORTHWESTERN NEVADA--PART I, GEOLOGY AND GEOPHYSICS,
Geological Survey, Boise, ID. Water Resources Div.
D. H. Schaefer, A. H. Welch, and D. K. Maurer.
USGS Open-File Report 81-918, 1983. 37 p, 15 Fig, 3 Tab, 52 Ref.

Descriptors: *Geothermal studies, Gravimetric prospecting, *Geophysical prospecting, Black Rock Desert, *Nevada.

Studies of the geothermal potential of the western arm of the Black Rock Desert in northwestern Nevada included a compilation of existing geologic data on a detailed map, a temperature survey at 1-meter depth, a thermal-scanner survey, and gravity and seismic surveys to determine basin geometry. The temperature survey showed the effects of heating at shallow depths due to rising geothermal fluids near the known hot spring areas. Lower temperatures were noted in areas of probable near-surface ground-water movement. The thermal-scanner survey verified the known geothermal areas and showed relatively high-temperature areas of standing water and ground-water discharge. The upland areas of the desert were found to be distinctly warmer than the playa area, probably due to low thermal diffusivity resulting from low moisture content. The surface geophysical surveys indicated that the maximum thickness of valley-fill deposits in the desert is about 3,200 meters. Gravity data further showed that changes in the trend of the desert axis occurred near thermal areas. (USGS)

AQUIFER SYSTEMS IN THE GREAT BASIN REGION OF NEVADA, UTAH, AND ADJACENT STATES--A STUDY PLAN,
Geological Survey, Boise, ID. Water Resources Div.
J. R. Harrill, A. H. Welch, D. E. Prudic, J. M. Thomas, and R. L. Carman.
USGS Open File Report 82-445, 1983. 49 p, 18 Fig, 39 Ref.

Descriptors: *Aquifer systems, *Regional analysis, Ground water, Geohydrology, Mathematical models, *Great Basin, *Regional aquifer system, *Nevada, *Utah.

The Great Basin Regional Aquifer Study includes about 140,000 square miles in parts of Nevada, Utah, California, Idaho, Oregon, and Arizona within which 240 hydrographic areas occupy structural depressions formed primarily by basin-and-range faulting. The principal aquifers are in basin-fill deposits; however, significant carbonate-rock aquifers underlie much of eastern Nevada and western Utah. In October 1980, the U.S. Geologi-

cal Survey started a 4-year study to: (1) describe the ground-water systems, (2) analyze the changes that have led to the systems' present conditions, (3) tie the results of this and previous studies together in a regional analysis, and (4) provide means by which effects of future ground-water development can be estimated. A plan of work is presented that describes the general approach to be taken. It defines the major tasks necessary to meet objectives and defines constraints on the scope of work. The approach has been influenced by the diverse nature of ground water flow systems and the large number of basins. A detailed appraisal of 240 individual areas would require more resources than are available. Consequently, the general approach is to study selected 'typical' areas and key hydrologic processes. Effort during the first three years will be directed toward describing the regional hydrology, conducting detailed studies of 'type' areas and studying selected hydrologic processes. Effort during the final year will be directed toward developing a regional analysis of results. Special studies will include evaluation of regional geochemistry, regional hydrogeology, recharge, ground-water discharge, and use of remote sensing. Areas to be studied using ground-water flow models include the regional carbonate-rock province in eastern Nevada and western Utah, six valleys--Las Vegas, Carson, Paradise, Dixie, Smith Creek, and Stagecoach--Nevada, plus Jordan Valley, the Millford area, and Tule Valley in Utah. The results will be presented in a series of reports that will summarize findings, hydrologic principles, and techniques that can be applied throughout the Great Basin. (USGS)
W84-01008

HYDROGEOLOGY AND SIMULATION MODEL OF WATER FLOW IN THE KOOTENAI AQUIFER OF THE JUDITH BASIN, CENTRAL MONTANA,
Geological Survey, Helena, MT. Water Resources Div.
J. F. Levings.
USGS Water-Resources Investigations, Report 83-4146, September 1983. 39 p, 15 Fig, 35 Ref.

Descriptors: *Model studies, Computer models, *Groundwater, *Geohydrology, Structural geology, Judith basin, Fergus County, Judith Basin County, *Montana.

Five Jurassic and Cretaceous formations in the Judith basin of central Montana were investigated with a three-dimensional model to improve the understanding of water flow in the Kootenai aquifer. To accomplish this objective, of water flow in the aquifers and two intervening confining layers was constructed from existing data. A steady-state model was calibrated and evaluated using a parameter-estimation procedure. The digital model simulates horizontal flow in the middle (Kootenai) aquifer and vertical leakage through the overlying and underlying confining layers. The top and bottom aquifers are used as constant-head boundaries to aid in simulating vertical leakage. Transmissivity for the aquifer obtained from the calibrated model ranges from 137 to 364 ft super 2/d. Recharge in the form of precipitation on the outcrop is about 2% of total precipitation (5.44 ft super 3/s). The other component of net recharge is 32.48 ft super 3/s of vertical leakage from the Swift aquifer. The cumulative rate of discharge from all known wells completed in the aquifer is about 0.84 ft super 3/s. Other components of net discharge are 1.83 ft super 3/s of underflow and 35.25 ft super 3/s of vertical leakage to the Colorado aquifers. Estimates of vertical hydraulic conductivity are 2.15 x 10- super 2 ft/d for the lower confining layer, and 3.16 x 10- super 3 and 1.33 x 10- super 4 ft/d for the upper confining layer. (USGS)

GEOHYDROLOGY OF THE FRESH-WATER AQUIFER SYSTEM IN THE VICINITY OF OCEAN CITY, MARYLAND,
Geological Survey, Towson, MD. Water Resources Div.
J. M. Weigle, and G. Aehmad.
Maryland Geological Survey, Baltimore, Report of Investigations No 37, 1982. 55 p, 29 Fig, 7 Tab, 29 Ref.

Descriptors: *Groundwater movement, *Confined groundwater, *Computer models, Hydrogeology, Aquifers, Groundwater recharge, Groundwater discharge, Potentiometric level, Hydraulic conductivity, Model studies, Saline water, Saline-water intrusion, Sea water, *Inter-aquifer leakage, Cone of depression, Groundwater flow model, Multilayer aquifer model, Quasi three-dimensional model, *Model simulations, Chloride concentration, Vertical leakage, Groundwater withdrawal, Hydraulic stress, Cyclic water-level changes.

Fresh ground water in northeastern Worcester County is restricted to the upper 450 feet of Coastal Plain sediments. Water is available in the Pleistocene water-table aquifer and the Pocomoke, Ocean City, and Manokin artesian aquifers. The sediments, water table, and potentiometric surfaces slope generally east-southeastward. The hydrogeologic structure in the study area continues offshore for at least several miles. Recharge from precipitation in the western part of the area affects all the freshwater aquifers. Under nonpumping conditions, discharge occurs primarily by upward leakage in the eastern part of the area and offshore. Lateral ground-water movement is east-south-eastward. Salty water occurs in the ocean and back bays near Ocean City, and possibly offshore in the Manokin aquifer. Also, at Ocean City some salty water has apparently leaked upward into the basal part of the Manokin aquifer from the underlying St. Marys Formation. Water needs for Ocean City and the nearby mainland are expected to substantially increase and most of this water will probably be withdrawn from the freshwater aquifers underlying the area. Simulation of alternate groundwater development plans with an uncalibrated model indicates that dispersal of pumping centers may spread drawdown cones and may reduce the magnitudes of drawdowns. WATER RESOURCES OF THE SANTA FE RIVER BASIN, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
J. D. Hunn, and L. D. Slack.
USGS Water-Resources Investigations Report 83-4075, 1983. 105 p, 30 Fig, 9 Tab, 41 Ref.

Descriptors: *Groundwater resources, *Aquifers, *Aquicludes, *Streamflow, *Water quality, Surface-ground-water relationships, Lakes, Springs, Groundwater recharge, Karst, Dissolved solids, Hardness, Sulfates, Low flow, *Santa Fe River Basin, Suwannee basin, *Florida, Floridan aquifer, Surficial aquifer.

The Santa Fe River basin is a 1,384 square-mile area in north-central Florida. The principal source of water is the Floridan aquifer, a sequence of limestone beds, the upper 300 to 800 feet of which contain potable water. The western part of the basin has the greatest potential yields for individual wells, as much as 5,000 gallons per minute, and contains the largest surface-water supplies. Spring discharge and diffuse seepage from the Floridan aquifer augment the Santa Fe River. The Floridan aquifer is overlain by a confining bed that in the western part of the basin is ineffectual. In the eastern part the Floridan aquifer is confined and the confining bed is overlain by a surficial aquifer. The confining bed contains water-yielding zones, which in addition to the surficial aquifer, may supply water for domestic use. Numerous tributary streams supply small amounts of water to the Santa Fe River and its principal tributary, New River. The base flow of most of these streams is supplied by the surficial aquifer. Estimated water use is about 17 million gallons per day, and runoff from the basin is estimated to be 1,400 million gallons per day. (USGS)

ASSESSMENT OF THE INTERCONNECT BETWEEN TAMPA BAY AND THE FL DAN AQUIFER, FLORIDA,
Geological Survey, Tallahassee, FL. Water
sources Div.
C. B. Hutchinson.
Available from National Technical Inform Service, Springfield, VA 22161 as ADA-13(Price codes: A04 in paper copy, A01 in microfi USGS Water-Resources Investigations Repor 54, 1983. 55 p, 23 Fig, 5 Tab, 58 Ref.

Descriptors: *Saline water intrusion, *Comp models, Groundwater movement, Hydrogeol Dredging, Water management(Applied), Leak Floridian aquifer, Tampa Bay, *Florida.

Factors that control interflow between Tampa and the Floridan aquifer are assessed, both qua tively and quantitatively, with emphasis on impact of harbor improvement. Hydrogeol units underlying the 350-square-mile bay incl the surficial-sand aquifer, upper sand and clay fining bed, and limestone of the Floridan aqu The surficial aquifer and upper confining bed h been eroded away in several areas along the no ern coast of the bay to directly expose the Flori aquifer to saltwater. There also, the top of aquifer is, has been, or will be exposed to saltw in numerous channels dredged in the Saltwater-freshwater relations indicate that degree of bay-aquifer interconnection decre from north to south. Saltwater intrusion is oc ring along the coast of Tampa Bay, as indicated reduction or reversal of potentiometric-surf gradients and increasing chloride concentration coastal monitoring wells. A computer model ground-water flow developed for a 97-square-m area was interrogated under five options of ch nelization and pumping. Model results indicate the total impact of channelization upon bay-aqu interconnection are expected to be small and m be imperceptible when considered over the l term with other unknown changes in climate development. R RESOURCES OF MANATEE COUNTY DA,
gical Survey, Tallahassee, FL. Water Re- Div.
Brown.
ble from the National Technical Information , Springfield, VA 22161 as PB83-218396, odes: A06 in paper copy, A01 in microfiche. Water Resources Investigations Report 81- 3. 112 p, 38 Fig, 19 Tab, 87 Ref.

ptors: *Surface water resources, *Ground- resources, *Water quality, Water utilization, rk design, Aquifers, Manatee County, da, Floridan aquifer.

development of Manatee County in south- lorida is creating water-resource problems. eport presents an evaluation of the water es and potential effects of water-resource pments. Most streams in the county have drainage basins and minimal flow. Stream- variable with the base flow occurring from ber to May. The Manattee River and its tributary, the Braden River, are the princi- urces of public supplies. Surface water is lly of good quality and less mineralized than water except in the tidally affected and area. The principal aquifers in the county surficial, minor artesian, and the Floridan. oridan aquifer is the major source of irriga- ater in the county. The minor artesian is a highly developed source of water for ural supplies. Withdrawals of 20 to 50 mil- llons per fay from the Floridan aquifer since 50's have caused declines in the potentiome- rface of about 20 to 50 feet. The quality of water is good except in the coastal and rn parts of the county. Water in the Floridan is generally more mineralized than the quifers, generally increasing in mineral con- th depth and from the northeast towards the est. (USGS)

OGEOLOGY OF THE PROVIDENCE FER OF SOUTHWEST GEORGIA,
Geological Survey, Doraville, GA. Water Resources Div.
J. S. Clarke, E. Faye, and R. Brooks.
Georgia Department of Natural Resources, Atlanta, Hydrologic Atlas No 11, 1983. 49 p, 16 Fig, 5 Tab, 25 Ref.

Descriptors: *Georgia, *Hydrogeology, Subsurface mapping, Groundwater, *Aquifer characteristics, *Potentiometric level, Groundwater, *Aquifer characteristics, *Potentiometric level, Groundwater recharge, Leakage, Groundwater movement, Groundwater divide, Water-level fluctuations, Chemical analysis, Water use, Well drilling, Upper cretaceous, Lower tertiary, Chattahoochee River, Flint River, Ocmulgee River, Providence Aquifer.

The predominantly sand Providence aquifer lies within the Coastal Plain physiographic province of southwest Georgia and ranges in thickness from 38 to 386 feet. Estimated transmissivities range from 760 feet squared per day in Schley County to 4,600 feet squared per day in Clay County. Recharge water enters the aquifer in the eastward trending outcrop belt and flow southward, bounded by the Ocmulgee River on the east and the Chattahoochee River on the west. Additional recharge is received through leakage from underlying units. Ground water is discharged from the aquifer to streams both in the outcrop area and downdip through overlying units. Idle multiaquifer wells in Albany and Dawson provide conduits for upward discharge of water from the Providence aquifer. (USGS)

EFFECTS OF GROUND-WATER DEVELOPMENT IN THE NORTH FORT HOOD AREA, CORYELL COUNTY, TEXAS,
Geological Survey, Austin, TX. Water Resources Div.
W. M. Sandeen.
USGS Water-Resourses Investigations Report 83-4074, 1983. 49 p, 5 Fig, 8 Tab, 9 Ref.

Descriptors: *Groundwater, *Texas, Fort Hood, Coryell County, *Groundwater withdrawals, *Water-level declines, Slightly saline water.

Nearly all ground water in the North Fort Hood area, located in Coryell County in central Texas, is withdrawn from the Hensell and Hosston Members of the Travis Peak Formation. The total average annual rates of ground-water withdrawals, mostly for public supply, has steadily increased from nearly 0.5 million gallons per day during 1955 to more than 1.5 million gallons per day during 1980. The principal effect of the long-term development of ground water in the area has been a large decline of water levels in wells. The historical confined (artesian) conditions of the principal aquifer have changed to water-table conditions in some areas as the artesian head drops below the base of the confining layer due to pumping. The greater storage property of the unconfined system will decrease the rate of water-level declines. However, well yields will continue to decrease in relation to the general decline of hydraulic head in the aquifer. The ground water in the area is slightly saline with the concentrations of some constituents generally exceeding chemical-quality limits set by the U.S. Environmental Protection Agency for public-water supplies. The historical chemical changes in the ground water generally are insignificant and appear unrelated to the large declines of water levels of the area. (USGS)

Descriptors: *Aquifer tests, *Hydraulic conductivity, *Transmissivity, Drawdown curves, Recovery curves, Saline groundwater, Salts, Radioactive dating, *Utah, Water wells, Paradox Member, Hermosa Formation, *Salt Valley Anticline, Paradox basin, Grand County.

Six exploratory wells, were drilled into the cap rock underlying Salt Valley, Utah, for geologic, geophysical, and hydrologic data to augment information obtained from three previous test wells. Drilling of three other test holes was abandoned before reaching the zone of saturation; the upper 100 meters of cap rock is unsaturated. Within the saturated part of the cap rock, hydraulic heads generally decrease with depth and to the northwest in this part of the valley. Hydraulic conductivity of the cap rock, as determined from pumping tests, ranged from 0.000093 to 0.206 meters per day; as a result, natural ground-water flow rates in the cap rock are small. Water ranges from a calcium bicarbonate sulfate type on the western edge of the valley to a calcium magnesium sodium bicarbonate, sulfate, chloride type near the center of the valley. Carbon-14 specific activity for cap-rock water yielded an uncorrected age of about 17,000 to 26,000 years before present near the western edge of the valley and about 1,000 years before present near the center of the valley. GROUND-WATER RESOURCES OF RANSOM AND SARGENT COUNTIES, NORTH DAKOTA,
Geological Survey, Bismarck, ND. Water Resources Div.
C. A. Armstrong.
North Dakota Geological Survey, Bismarck, Bulletin 69, 1982. 51 p, 14 Fig, 3 Tab, 48 Ref.

Descriptors: *Water resources, *Ground water, *Aquifers, Transmissivity, Recharge, Water use, Chemical properties, Potential yield, Ransom County, Sargent County, *North Dakota.

Ground water in Ransom and Sargent Counties is available from the Dakota aquifer system of Cretaceous age and from aquifers in the glacial drift and alluvial aquifers Quaternary age. The Dakota aquifer system has a greater areal extent, but aquifers in the glacial drift provide a greater yield to individual wells. The Dakota aquifer system generally yields less tha 50 gallons per minute to wells. The water ranges from soft to very hard and is a sodium sulfate or sodium chloride type. Glacial-drift aquifers consist of sand and gravel deposits in buried valleys and glacioaqueous deposits in Ransom and Sargent Counties. These aquifers underlie about 690 square miles and contain an estimated 3,000,000 acre-feet of available ground water. Potential well yields range from 50 to 1,500 gallons per minute. The water generally is hard and is a calcium or sodium bicarbonate type. The rural population and all communities in Ransom and Sargent Counties depend on ground water as their source of supply. 2G. Water In Soils

MATHEMATICAL MODELS OF SOIL MOISTURE PROFILES USING TWO-PHASE FLOW THEORY,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
H. J. Morel-Seytoux.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-140599, Price codes: A04 in paper copy, A01 in microfiche. Colorado Water Resources Research Institute Completion Report No 127, Colorado State Univ., Fort Collins, July 1983. 58 p, 3 Fig, 1 Tab, 5 Ref. OWRT B-207-COLO(1), 14-34-0001-0260.

Descriptors: *Model studies, *Mathematical studies, *Finite difference methods, *Soil water, *Infiltration, *Soil moisture profiles, Two-phase flow theory.

Three methods of analysis for prediction of infiltration and water content profiles in a soil column are

presented. The first method is the more or less classical finite difference approach except that the governing equations are those deduced from two-phase flow theory. As a result the determination of the water content at the soil surface before ponding is facilitated. Similarly, after ponding the calculation of the capacity infiltration rate is more stable than with the usual finite difference approximations to Richard's equation. The second method is purely analytical. It 'speaks' as results such as ponding time are obtained explicitly in terms of the various parameters of the problem (hydraulic conductivity, effective capillary drive, initial water content, etc.). Each solution applies for a particular value of the exponent n in the power law form of the relative permeability vs. normalized water content curve. Solutions have been obtained for n = 1,2,3,4,6 and 8. Profiles look realistic. Nevertheless, the results are approximate. A third method, a hybrid method, tries to combine the advantages of the numerical and analytical techniques by retaining the versatility of the numerical method and the low cost of the analytical method. The hybrid method is illustrated in depth for the case n = 1. The case n = 2 has been discussed previously in the literature (Morel-Seytoux, 1982). Results for the case n = 4 are given without derivation. The case n = 4 has been implemented operationally in a computer program SOILMOP. Tests (though limited) indicate that accuracy with SOILMOP is comparable with existing difference code for the Richar's equation and is 25 times cheaper. The hybrid technique appears to have a significant potential.

HYDRAULIC CONSIDERATIONS IN SAMPLING THE UNSATURATED ZONE WITH INCLINED GRAVITY LYSIMETERS,
Geological Survey, Albany, NY. Water Resources Div.
E. T. Oaksford.
USGS Water-Resources Investigations Report 83-4005, 1983. 17 p, 12 Fig, 9 Ref.

Descriptors: *Gravity lysimeters, *Water sampling, *Unsaturated zone, *Soil water, Suffolk County, Long Island, *New York.

Inclined gravity lysimeters as deep as 5.39 meters below land surface designed for sampling soil water in coarse sand under continuous ponding conditions, were shown to be capable of collecting 10 liters per hour at an infiltration rate of 0.5 meter per hour. This represents a capture efficiency of approximately 50%, a value observed in two similar but shallower lysimeters. When lysimeters are installed from a trench or observation manhole, soil-water samples can be taken under virtually undisturbed conditions, avoiding the soil disturbance and filtration associated with porous-cup vacuum lysimeters. Successful operation requires that the sampler be designed for the hydraulic characteristics of the soil from which the water sample is to be extracted. Criteria for lysimeter dimensions can be established on the basis of pressure heads experienced during sampling, can be induced to flow into the lysimeter by gradient manipulation. Observed head gradients outside the lysimeter ranged between 1.7 and 2.2 times those across the lysimeter, which would seem to explain the observed capture efficiency. (USGS)

2H. Lakes

LIMNOLOGICAL CHARACTERISTICS OF WISCONSIN LAKES,
Wisconsin Dept. of Natural Resources, Madison.
R. A. Lillie, and J. W. Mason.
Technical Bulletin No 138, 1983. 116 p, 84 Fig, 43 Tab, 184 Ref, 2 Append.

Descriptors: *Lakes, *Limnology, *Lake morphometry, *Chemical analysis, *Trophic level, *Water quality, Water sampling, Thermal stratification, Chlorophyll A, Macrophytes, Alkalinity, Phosphorus, Nutrients, Secchi disks, Chlorides, Cations, Sulfates, Nitrogen, Water quality management, *Wisconsin.

A 14-year study of Wisconsin lakes began in 1966 when the Wisconsin Legislature recognized the need for data on the state's water resources. This report is intended as a technical reference for professionals in water-related fields. A random selection of 1,140, or 25% of Wisconsin lakes, all greater than 5 feet deep and 25 acres in size, comprised the data base. Water samples were collected and subjected to physical, chemical and biological analyses. These results, with field notes and known morphometric characteristics, formed the core of the data used in the study. The data allowed the evaluation and examination of general limnological characteristics of Wisconsin lakes. An apparent water quality index is presented for Wisconsin lakes, incorporating water clarity, chlorophyll concentration, and total phosphorus. Preferably, all three parameters should be used in evaluating a lake. Strong relationships exist between a great number of measured physical, chemical, and biological parameters. On the other hand, a considerable amount of scatter occurs in plots of the various interrelationships, which suggests that caution must be used in applying linear regression formulae derived from these associations for predictive purposes. Assessment of trends in water quality is restricted by insufficient data. The substantial amount of individual lake data collected and analyzed should be useful as a historical data base for evaluating future trends in water quality for sampled lakes. (Fazio-Omniplan)

COMPUTER SIMULATION OF PHOSPHORUS CYCLING IN THE SEDIMENT-WATER SYSTEM OF EUTROPHIC LAKES,
Maine Univ. at Orono. Dept. of Mathematics.
T. A. Hannula, and C. A. Rock.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-140573, Price codes: A08 in paper copy, A01 in microfiche. Land and Water Resources Center Completion Report, August 1983. 156 p, 38 Fig, 8 Tab, 19 Ref, 1 Append. OWRT B-021-ME(1), 14-34-0001-1231.

Descriptors: *Computer models, *Cycling nutrients, *Diagenesis, *Lake sediments, *Phosphorus, Adsorption, Anaerobic conditions, Boundary conditions, Decomposing organic matter, Diffusion coefficient, Eutrophic lakes, Interstitial water, Mathematical models, Porosity, Radioactive dating, Recycling, Seasonal Variation, Vertical Distribution, *Maine, Lake Sebasticook.

It has become increasingly evident that the release of phosphorus from the sediments of eutrophic lakes is a major factor in the excessive productivity of these lakes. Using the diagenic partial differential equations which model the sediment processes of lakes and oceans, a computer simulation model has been developed to study the P dynamics in lake sediments. The model allows both time and depth variation of the key equation parameters. The model clearly shows that the upper 10 cm of sediment is the main region of activity. The lowering of the sorption coefficient and PIW increase are the most significant factors in a large summer P release from the sediment. The rapid burial and decomposition of organic matter in the top few centimeters of sediment in these productive lakes is sufficient to maintain the pore water and sorbed P at levels needed to support a large summer P release. The model generates summary tables and 3D plots of key variables over a year's simulation. The Numerical Method of Lines is used to solve the model equations. Data from L. Sebasticook, Newport, Maine are used to test the model.

HYDROLOGY OF WISCONSIN, WETLANDS,
Geological Survey, Albany, NY. Water Resources Div.
R. P. Novitzki.
University of Wisconsin-Extension, Madison, Geological and Natural History Survey, Information Circular No 40, 1982. 22 p, 14 Fig, 7 Tab, 34 Ref.

Descriptors: *Wetlands, Floods, Base flow, Sediment yield, *Wisconsin wetlands, *Hydrologic wetlands classification.

The hydrologic characteristics of Wisconsin's w
lands, and their effect on floodflows and b
flows, are described. Wetlands occur in depres
and on slopes, and may be in contact with gro
water or totally surface-water supported. Wisc
sin's wetlands can be classified as surface-w
depression, ground-water depression, surfa
water slope, or ground-water slope. Through
the State, floodflows are 80% lower, springti
streamflows 40% higher, and fall base flows 4
lower in basin with 40% lake and wetland a
than in basins with no lake and wetland area. In
north-central third of the State sediment yields
90% lower in basins with 40% lake and wetl
area. (USGS)

Descriptors: *Lakes, *Hydrologic budget, *Nut
ents, *Water pollution sources, *Washington, Ki
County, Pine Lake, Lake restoration.

An adjusted water budget prepared for Pine La
a candidate for lake-quality restoration, indica
that of approximately 790 acre-feet of water th
enters the lake in a typical year, 410 acre-feet
from precipitation, 350 acre-feet is from surfa
inflow, and 30 acre-feet is from ground-water see
age. A nearly equal amount of water leaves t
lake and of this, 130 acre-feet is by evaporatio
659 acre-feet is by surface runoff, and less than o
acre-foot is by ground-water seepage. Based
these amounts of inflow and outflow, the theore
cal water-renewal time of the lake is calculated
be 2.2 years. The contributions of inorganic nitr
gen and phosphorus to the lake in a typical ye
from precipitation, surface inflow, and groun
water inflow is about 2,500 pounds of nitrogen a
49 pounds of phosphorus. (USGS)

County, Carbon County, Data collection, Franc
E. Walter Reservoir, *Pennsylvania.

Water-quality data, both past and present, sho
that the waters of the upper Lehigh River basin a
somewhat acidic, but otherwise are generally
good quality. This report is a summary of a
known water-quality data collected by the U.S
Geological Survey and other agencies, includes
synopsis of current water-quality conditions in th
reservoir and its tributaries. Data collected fro
June 1981 to May 1982 indicate that raising th
pool an additional 92 feet had some significant,
only temporary, detrimental effects on the rese
voir system. Depth profile measurements sho
that the dissolved oxygen concentrations were de
pressed to near-aquifer levels, and the median p
values were depressed from 6.5 to 6.0. (USGS

nc.
en-File Report 83-212, March 1983. 22 p, ab, 6 Ref.

rs: *Sediment discharge, *Sediment load, ow, *Particle size, Small watersheds, ration watersheds, Soil conservation, ta, Winona County.

w and suspended-sediment-transport data lected in Garvin Brood watershed in County, Southeastern Minnesota, during e data collection was part of a study to the effectiveness of agricultural best- ent practices designed to improve rural ality. The study is part of a Rural Clean ogram demonstration project undertaken S. Department of Agriculture. Continu- nflow data were collected at three gaging luring March through September 1982. d-sediment samples were collected at two aging stations. Samples were collected at weekly intervals. During periods of hanging stage, samples were collected at to 12-hour intervals by stage-activated samplers. The samplers were analyzed nded-sediment concentration and particle- ibution. Particle-size distributions were rmined for one set of bed-material samples at each sediment-sampling site. The w and suspended-sediment-concentration e used to computer records of mean-daily an-daily suspended-sediment concentra- daily suspended-sediment discharge. The ords are documented and results of analy- particle-size distribution and of vertical in the stream cross sections are given.

STREAMFLOW AND SEDIMENT TRANSPORT IN THE QUILLAYUTE RIVER BASIN, WASHINGTON,
Geological Survey, Tacoma, WA. Water Resources Div.
L. M. Nelson.
Available from the USGS, OFSS, Lakewood, CO 80225, Price: $4.25 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-627, 1982. 29 p, 11 Fig, 7 Tab, 19 Ref.

Descriptors: *Sediment, Sediment transport, *Sediment yield, Bedloads, *Low flows, Streamflows, Land use, Jefferson County, Clallam County, Quillayute River, *Washington.

From October 1976 to September 1978 the U.S. Geological Survey made a reconnaissance evaluation of the fluvial-sediment transport and documented the natural streamflow characteristics in the Quillayute River basin in northwestern Washington. Most of the flow originates from the tributaries, the Soleduck, Bogachiel, and Calawah Rivers. Flow in the summer months from the Calawah River is about half that from either the Bogachiel or Soleduck Rivers. In the winter months flow from the Soleduck River is about 1 1/2 times that of the Bogachiel or Calawah Rivers. In general, the highest monthly flows during the winter are about 10 times greater than the lowest monthly flows during the summer except for the Dickey River where winter flows are about 20 times greater. Annual mean discharges may vary greatly from year to year, ranging from about 1/2 to 1 1/2 times the mean annual discharge. For the study period, the observed suspended-sediment concentration ranged from less than 1 to 2,150 milligrams per liter. The estimated mean annual suspended-sediment discharges were: Bogachiel River--400,000 tons (includes Calawah River); Calawah River--120,000 tons; Soleduck River--120,000 tons; Dickey River--75,000 tons; and other tributaries--10,000 tons, for a total of 606,000 tons transported annually by the Quillayute River. The estimated annual bedload of 21,000 tons was transported into the Quillayute River by the Soleduck, Bogachiel, and Dickey Rivers. (USGS)

AN EVALUATION OF SUSPENDED SEDIMENT AND TURBIDITY IN COW CREEK, OREGON,
Geological Survey, Portland, OR. Water Resources Div.
D. A. Curtiss.
Available from the USGS, OFSS, Lakewood, CO 80225, Price: $3.25 in paper copy, $3.50 in microfiche. USGS Water Resources Investigations Open-File Report 82-364, 1982. 21 p, 11 Fig, 4 Tab, 9 Ref.

Descriptors: *Sediments, *Sediment transport, *Turbidity, Fluvial sediments, Sediment distribution, Settling velocity, *Residual turbidity, *Clay transport, *Oregon, Douglas County, Cow Creek.

During a 6-month period from December 1980 through May 1981, samples were collected from Cow Creek near Azalea, Oregon, and analyzed for suspended sediment, particle-size distribution, and turbidity. Of the estimated suspended-sediment discharge of 4,270 tons for the 1981 water year, 95% (4,050 tons) was transported during a major storm event December 2-4, 1980. The 1981 water year suspended-sediment discharge of 4,270 tons is well below the average annual suspended-sediment discharge of 22,000 tons reported earlier by Curtiss. A clay-sediment transport curve was used in conjunction with the flow-duration curve to estimate average annual clay discharge of 3,700 tons for Cow Creek near Azalea. Turbidity in Cow Creek near Azalea is estimated to be equal to or less than 15 NTU (nephelometric turbidity units) 90% of the time. A method for predicting turbidity values in a hypothetical impoundment is presented in this report. This method utilizes a suspended-sediment transport curve of the fine material (<0.002 mm) and measure residual-turbidity values. (USGS)

MINERALOGY OF FINE-GRAINED ALLUVIUM FROM BOREHOLE U11G, EXPL. 1, NORTHERN FRENCHMAN FLAT AREA, NEVADA TEST SITE,
Geological Survey, Reston, VA. Water Resources Div.
B. F. Jones.
USGS Open-File Report 82-765, 1982. 10 p, 1 Fig, 3 Tab, 12 Ref.

Descriptors: *Mineralogy, *Clays, *Zeolites, *Alluvium, Water table, Hydration reactions, Weathering, Volcanic glass, Chemical analyses, *Nevada, Frenchman Flat, Smectite, Sepiolite, Interstratified minerals.

The mineralogy of matrix fines in alluvium from borehole Ullg, expl. 1, north of Frenchman Flat, Nevada Test Site, has been examined for evidence of past variations in water table elevation. Although greater abundance of zeolite and slightly more expanded basal spacings in smectite clays suggest effects of increased hydration of material up to 50 m above the present water table, these differences might also be related to provenance of environment of deposition. The relative uniformity of clay hydration properties in the 50 meters above the current water table suggest long-term stability near the present level. (USGS)

MICROCOMPUTER COMPUTATION OF WATER QUALITY DISCHARGES,
Geological Survey, Columbus, OH. Water Resources Div.
D. R. Helsel.
USGS Open-File Report 82-901, 1983. 48 p, 7 Fig, 2 Tab, 2 Ref.

Descriptors: *Computer programs, *Water quality, *Sediment discharge, Hydrographs, Suspended land.

A fully prompted program (SEDQ) has been developed to calculate daily and instantaneous water quality (QW) discharges. It is written in a version of BASIC, and requires inputs of gage heights, discharge rating curve, shifts, and water quality concentration information. Concentration plots may be modified interactively using the display screen. Semi-logarithmic plots of concentration and water quality discharge are output to the display screen, and optionally to plotters. A summary table of data is also output. SEDQ could be a model program for micro and minicomputer systems likely to be in use within the Water Resources Division, USGS, in the near future. The daily discharge-weighted mean concentration is one output from SEDQ. It is defined in this report, differentiated from the currently used mean concentration, and designated the 'equivalent concentration.' (USGS)

EROSION AND SEDIMENT CHARACTERISTICS OF THE SOUTHEASTERN UINTA BASIN, UTAH AND COLORADO,

Geological Survey, Salt Lake City, UT. Water Resources Div.
R. L. Seiler, and J. E. Tooley.
USGS Water-Resources Investigations Open-File Report 82-428, 1982. 44 p, 22 Fig, 10 Tab, 37 Ref.

Descriptors: *Sediment discharge, *Oil shale, *Utah, *Colorado, *Sediment yield, Channel erosion, Deposition, Particle size, Gully erosion, Unita Basin, White River, Source area sediment yield.

This report is part of a series describing the hydrologic characteristics of the southeastern Uinta Basin of Utah and Colorado, area of about 3,000 square miles. The mean annual suspended-sediment discharge of the White River at its mouth near Ouray (1975-79) was 1,759,000 tons (1,150 acre-feet) and for the White River near Colorado-Utah state line (1977-79) sediment discharge was 1,031,000 tons (675 acre-feet). The total-sediment yield for the area between these two stations for the period of concurrent record is calculated to be about 900 tons (0.59 acre-foot) per square mile per year. During snowmelt runoff from the lower basin (March) and later during snowmelt runoff from the upper basin (May and June) there are periods of large, sustained sediment discharges in the White River. During late summer, sediment discharge can increase significantly in response to thunderstorm runoff from normally dry tributaries. Large amounts of bed material are scoured from the lower White River channel during the annual peak flow, however, the mean streambed altitude does not change much because an equivalent amount of material is deposited in the channel during peak flow recession. (USGS)

WATER-QUALITY AND FLUVIAL-SEDIMENT CHARACTERISTICS OF SELECTED STREAMS IN NORTHEAST KANSAS,
Geological Survey, Lawrence, KS. Water Resources Div.
H. E. Bevans.
USGS Water Resources Investigations Report 82-4005, 1982. 53 p, 2 Fig, 15 Tab, 17 Ref.

Descriptors: *Agricultural watersheds, *Water analysis, *Suspended sediments, *Chemical analysis, Sediment discharge, Sediment concentration, Streamflow, Statistical analysis, *Kansas.

In cooperation with the U.S. Soil Conservation Service, an investigation was made of the water-quality and fluvial-sediment characteristics of selected streams in northeast Kansas for which the construction of floodwater-retarding and grade-stabilization structures to control soil erosion is being considered. The predominent chemical type of water in streams draining the study area is calcium bicarbonate. In-stream concentrations of chemical constituents generally decrease with increasing streamflow. Exceptions to this are nitrate and phosphorus, which enter the streams as components of surface runoff. Computed mean annual discharges of dissolved solids ranged from 512 tons for Pony CratkSabetha, Kansas, to 23,900 tons for the Wolf River near Sparks, Kansas. Sediment yields in the study area, predominently silt and clay, are among the largest in the State. Drainage basins in the northern part of the study area yielded the most suspended sediment, with Pony Creek at Sabetha and near Reserve, Kansas, yielding 5,100 tons per square mile per year. Drainage basins in the southern part of the study area yielded less suspended sediment, with Little Grasshopper Creek near Effingham, Kansas, yielding 493 tons per square mile per year and Little Delaware River near Horton, Kansas, yielding 557 tons per square mile per year. UTILIZATION OF THE NEW MINERAL UF MEMBRANES FOR MAKING SEMI-HARD CHEESES,
Institut National de la Recherche Agronomique, Rennes (France). Dairy Technology Research Lab.
H. Goudedranche, J. L. Maubois, P. Ducruet, and M. Mahaut.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29 - Oct. 1, 1980), p 243-258, 3 Tab, 8 Fig, 14 Ref.

Descriptors: *Membranes, Mineral membranes, *Ultrafiltration, *Cheese, Milk.

By using an ultrafiltration (UF) apparatus equipped with new mineral membranes making it possible to reach a protein content of 21% and a T.S. Content of 45%, making semi-hard cheese such as the French variety St. Paulin was studied. Properties of precheeses were characterized for defining optimum parameters of the proposed process. Acidification, addition of salt, renneting pH, and temperature were studied for their influence regarding the rheological behavior of the precheese and/or the organoleptic qualities of young and ripened cheese. Advantages of the process (increase of 19% of the cheese yield, no in-vat processing, possible addition of flavouring substances) are discussed. Performances observed with the new UF equipment (30 l of milk treated per hour per sq m) and its cleanability offer sufficient reliability to envisage an industrial scale up.

BIOCATALYSIS BY MEMBRANE-ATTACHED ENZYMES AND WHOLE MICROBIAL CELLS,
(Heinz (H.J.) Co., Pittsburgh, PA.
K. Venkatsubramanian.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29 - Oct. 1, 1980), p 353-363, 8 Tab, 5 Ref.

Descriptors: *Membranes, *Enzymes, Biocatalysis, Microbial cells, Collagen, *Microbiological studies.

Bioconversion processes employing fixed enzymes and whole microbial cells is becoming a well-established art. A wide variety of inorganic and organic carrier matrices, as well as immobilization procedures, were employed for immobilizing enzymes or microbial cells. While the preferred physical form of these biocatalysts often tends to be pellets or beads used in a packed bed reactor, the membranous form offers several unique advantages over such reactor designs. Research effort was expended over the past decade in the development of biocatalytic reactor systems based on enzymes and cells immobilized on reconstituted collagen membranes. The key features of biocatalysis are highlighted.

MEMBRANE TECHNOLOGY APPLIED TO BIOCONVERSION OF MACROMOLECULAR SUBSTRATES AND UPGRADING OF PRODUCTS. A MODEL STUDY ON ETHANOL PRODUCTION FROM CELLULOSE,
Lund Univ. (Sweden). Dept. of Technical Microbiology.
B. Hagerdal, M. Lopez-Leiva, and B. Mattiasson.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29 - Oct. 1, 1980), p 365-373, 1 Tab, 5 Fig, 26 Ref.

Descriptors: *Membranes, Economics, *Reverse osmosis, Bioconversion, Enzymes, Cellulose, Ethanol, *Alcohols, Separation techniques.

The use is discussed of membrane reactors for enzymatic degradation of macromolecular substrates in order to reduce product inhibition. In this study the degradative step is integrated with a process line containing reverse osmosis as well as bioconversion utilizing co-immobilized enzymes and microorganisms. This concept of a combination of membrane technology and biotechnology takes into account not only the fact that bioconversions generally are controlled by product inhibition but also that dilute product solutions will be obtained when these bioconversions are continuously operated. Bioconversions have to be optimized with respect to productivity as well as product concentration. When taking membrane technology into account these optimizations may concentrate more on productivity since the resulting dilute product stream can be upgraded in a suitable membrane unit operation.

MEMBRANE TECHNOLOGY AND COSTS; STATE OF THE ART,
Lund Univ. (Sweden). Dept. of Business Administration.
B. Bjerke.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29 - Oct. 1, 1980), p 375-382.

Descriptors: *Membranes, *Economics, Reviews, Costs, Membrane processes, Separation techniques.

It is impossible to make calculations which are generally valid. There are too many assumptions which must be established before an individual case can be calculated, e.g., concerning volume treated, operating period, and membrane life. One can think of an 'average' situation looked at from such a systems level that components can be distinguished, i.e., (1) pretreatment, (2) reverse osmosis membranes (3) post-treatment (4) support systems, and (5) acceptance test. From this point of view one can easily find crucial factors such as membrane, operating/cleaning labor, and depreciation costs. Some industries are more suitable than others from an economic point of view, e.g. woodpulp, dairy, and foodstuff. Generally there are questions which are seldom asked. Such are the role of opportunity costs, start-up problems, and costs from help of experts. There are several advantages from using membrane technology for concentration, e.g. less need of energy, smaller installations, and environmental advantages. These factors will be stressed even more in the future. Membrane technology has therefore come to stay.

MEMBRANE LIFE, CAPACITY AND COSTS,
Paterson Candy International Ltd., Laverstoke (England).
D. Pepper.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29 - Oct. 1, 1980), p 383-396, 5 Tab, 5 Fig, 7 Ref.

Descriptors: *Membranes, Membrane processes, Seawater, Brackish water, *Costs, Dairy industry, Food processing industry, Chemical industry.

Membrane life is determined as much by the way that the system containing the membrane is designed and used as by the chemical and physical stability of the membrane. Membrane life is not a fundamental property of the membrane. All membranes suffer from a gradual loss of throughput because of creep under the applied stress but this is predictable and can be allowed for in design. Chemical attack can be quantified and operating limits set to minimise it. Membranes already exist with adequate lifetimes for the treatment of brackish and seawaters and for applications in the dairy, food, and pharmaceutical industries. Many other applications will become possible, for example in the chemical industries, when more resistant membranes are available.

MEMBRANE PROCESSES FOR WATER SUPPLY AND REUSE - A QUESTION OF ENERGY CONSUMPTION AND COST,
Vattenbyggnadsbyran Ltd., Stockholm (Sweden). Div. for Water, Soil and the Environment.
B. Ericsson.
Desalination, Vol 35, Nos 1/2/3, December 1980 (Comprising the Proceedings of the Symposium on Membrane Technology in the 80's, Ystad, Sweden, Sept. 29 - Oct. 1, 1980), p 401-421, 11 Tab, 9 Fig, 15 Ref.

Descriptors: *Desalination, Desalination plants, Brackish water, Seawater, *Water supply, Water reuse, Membrane processes, Reverse osmosis, Energy, Costs, MSF-RO dual-purpose,

Wastewater treatment, Multistage flash, Salbukh, Riyadh, Saudi Arabia.

Desalination of brackish water and seawater with reverse osmosis (RO), with special emphasis on costs and energy consumption, is discussed. Some aspects of and development trends in industrial and domestic applications of membrane processes are also taken up, particularly with regard to by-product recovery and water reuse in connection with advanced wastewater treatment. The first RO plant to be brought into operation in Riyadh, Saudi Arabia, is located at Salbukh. The investment and total operation costs for this plant have been calculated. The water cost is at least twice as high as in a continental U.S. location, due the very high cost of civil and local works in Saudi Arabia. A similar calculation has been made for RO seawater desalination. Increased energy costs during the last decade have directed R and D work for all desalination methods towards reducing energy consumption. Energy recovery in connection with RO seawater desalination is particularly feasible. Different methods for energy recovery are reported, the preferred methods depending on the size of the RO plant. A large underground RO plant for energy recovery, based on utilization of the static pressure instead of high pressure pumps, was studied. Another possible energy-saving, but also water quality improving method is proposed, viz. a combined multistage flash (MSF)-RO dual purpose plant. Excess power for RO seems to be more and more available in Saudi Arabia due to the high power/water ratio in MSF dual purpose plants compared to the real demand for power and water.

DISTRIBUTED CONTROL SYSTEMS FOR DESALINATION,
Catalytic, Inc., Philadelphia, PA.
E. V. Kelley.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 3-21, 7 Fig, 6 Ref. (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, *Computers, *Control systems.

Historically, desalination applications have not utilized direct computer control due to the relative simplicity of the typical desalination control systems, the cost of direct computer control, and the heretofore sophisticated operation and maintenance procedures required to implement a direct computer controlled system. As the size of desalination plants has increased for facilities in the Middle Eastern countries, the need for energy management and data acquisition has appeared in the form of ancillary computer systems in addition to the standard analog control system for the facility. An overview is presented of typical distributed control systems which have become more readily available in recent years. Emphasis is placed on the steps which have been taken by various manufacturers to simplify the implementation, operation, and maintenance of currently available systems and the importance of monitoring significant process variables which affect operating efficiency and the physical condition of the plant.

TODAY'S STATUS OF PH MEASUREMENT AND CONTROL IN DESALINATION PLANTS,
Foxboro Co., MA.
F. E. Moore.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 23-31, 4 Fig, 2 Ref. (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Instruments, *Multistage flash, *Reverse osmosis, *Hydrogen ion concentration, Acid-dosing, Electrolyte dosing.

Horror stories about desalination plants are rampant: acid-dosed multistage flash plants needing retubing after two years; electrolyte-dosed plants working a little longer, reverse osmosis plants needing new membranes in a few years. Some of these troubles are blamed on poor hydrogen ion concentration measuring equipment. In an effort to determine today's real situation regarding hydrogen ion concentration measurement, a survey was conducted of the entire membership of the International Desalination and Environmental Association. The results prompted further in-depth discussions with knowledgeable people in the desalination field. This paper is based on the survey, the in-depth discussions, and 20 years of experience in the hydrogen ion concentration measurement field.

is presented for a solar/thermal system
d to power a reverse osmosis (RO) desali-
it to produce 7000 gallons of fresh water
r period. A field of line-focus tracking
llectors is used to heat a high pressure
por water storage tank supplying two
d reciprocating steam engines, one direct-
d to the RO high-pressure pump and the
an electric generator for auxiliary power.
iary heating loop with an oil-fired boiler is
l to supply the steam engines. The system
in either all-solar, all-oil, or mixed solar/
s. Primary operating mode is assumed to be a mixed solar/oil mode in which the oil-fired boiler is used only to prevent shutdown of the RO system during the course of a partly sunny day. In this mode, the RO system does not come on line in the morning until the solar collector field has brought the high-pressure storage tank to a point near maximum operating pressure. Thereafter, the oil-fired boiler comes on automatically whenever the storage tank is drawn down to a pressure near minimum full-power operation (due to inadequate or intermittent insolation) and remains on, supplying the steam engines, until the solar collectors have again brought the storage tank to the high-pressure cutoff. In the all-solar mode, the system continues to operate at reduced power as storage tank pressure drops below the point at which the oil-fired boiler would otherwise come on. A portion of the RO system is shut down to maintain pressure in the remainder. The all-oil mode is used whenever fresh water is required during non-sunny periods, or to increase fresh water production in sunny periods.

SOLAR DISTILLATION: THE SOLAR-DRIVEN CASE,
Sydney Univ. (Australia).
J. P. Gerofi, G. G. Fenton, and E. Mannik.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 83-94, 8 Fig, 1 Tab, 14 Ref, (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Solar distillation, Economics, Solar stills.

Distillation systems are discussed where all the plant's thermal energy requirements are provided by solar energy. Fairly small capacity plants are considered operating in remote arid regions. Such systems consist of solar collectors and thermal storage coupled to a distillation plant. Each of these aspects is considered as well as the type of control strategy to be used. Using a dynamic computer simulation model, two solar-driven systems are considered: one using flat-plate collectors and a 76C multiple-effect evaporator (MEE) desalination plant, the other using evacuated tubular collectors and a 95C MEE plant. Various combinations of collector area and thermal storage volume are considered, and optimal values determined for each case. For the particular example chosen (100 cu m/day, located at 23 1/2 deg S) the flat-plate collector system was superior at current prices, giving an overall water cost of $5.82/cu m versus $7.34 for the second system. Both these costs are considerably less than water costs from conventional solar stills.
W84-00726

COMPARISON OF SOLAR RO AND SOLAR THERMAL DESALINATION SYSTEMS,
Sydney Univ. (Australia).
J. P. Gerofi, and G. G. Fenton.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 95-107, 1 Fig, 8 Tab, 11 Ref, (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Solar reverse osmosis, Solar distillation, Economics, *Solar energy, Reverse osmosis.

The unit water costs from 100 cu m/day solar reverse osmosis (RO) and solar distillation plants are compared. RO plants powered by photovoltaic cells are already available, and distillation plants operated from solar collectors are being constructed. For the size chosen and these options it is concluded that distillation is cheaper than RO for salinities above about 6,000ppm. Solar ponds can provide both thermal and electrical energy more cheaply than the above options, but they do not yet have the market penetration of the more accepted systems. If solar ponds are used then distillation is cheaper than RO only for salinities above about 10,000ppm.

DESIGN AND OPERATION EXPERIENCE WITH SOLAR POWERED MULTISTAGE DESALINATION PLANTS,
Ecole Polytechnique Federale de Lausanne (Switzerland).
R. Kriesi.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 109-116, 2 Fig, (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Solar energy, *Solar distillation, *Multistage flash, Distillation, Kuwait.

Desalination is a favourable application for solar energy and has a good potential for economic viability, since water demand is a consequence of abundant irradiation (no long term storage needed) and only low temperatures are necessary for the required thermal energy (simplicity of solar collector system). An R and D partnership for the development and implementation of solar desalination technology has been set up between the Swiss Federal Institute of Technology (fundamental development and laboratory testing), Atlantis Energy Ltd. (hardware design, construction and delivery) and the Kuwait Institute for Scientific Research (field testing). A 3-phase program is under way: Phase 1 (completed): Initial construction of a conventional MSF plant, laboratory and field tests. Design criteria for solar equipment resulted such as capability of operation under heavily fluctuating energy input conditions, minimization of mechanical energy consumption, simplicity of equipment, etc. Phase 2 (completed): Design of a new 'real solar' MSF-unit, meeting the above requirements, laboratory testing, field testing in Kuwait. Phase 3 (under way): Upscaling of the pilot plant to commercial sizes of 100 to 1000 cu m/day, optimization of the process, realization of a demonstration plant, coupled to a salt solar pond, specially developed for this purpose. Solar desalination has been demonstrated to be a reliable method of obtaining drinking water when using a specially developed salt solar pond system as heat source, water at lower prices is obtained compared with that from an oil-fired evaporator.

SOLAR DESALINATION: PROTOTYPE 'PITHON' A SPECIAL SOLAR MULTIPLE-EFFECT DISTILLER,
CEA Centre d'Etudes Nucleaires de Saclay, Gif-sur-Yvette (France).
J. C. Deronzier, F. Lauro, and R. Ployart.
Desalination, Vol 39, Nos 1/2/3, Dec. 1981, p 117-123, 4 Fig, (2nd Vol. Proc. of International Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Solar multi-effect distillation, Solar distillation, Arabian Gulf, 'Pithon' prototype, Hagevap treatment.

Solar distillation is one of the future solutions to producing fresh water from the sea or from brackish water. The international market capacities range from 100 to 200 or 300 cu m/d. The French Atomic Energy Commission has designed a new type of evaporator which permits a good adaptation to solar collectors under the conditions of Arabian countries. A horizontal submerged tube multiple-effect process is used, operating at low temperature under atmospheric pressure (T<70C) with Hagevap treatment. This process is well known in countries of the Arabian Gulf particularly in Kuwait. Operating at low temperatures avoids scaling and corrosion problems. Multiple-effect gives a very high performance ratio and low electrical consumption for pumping.

WIND AND SOLAR POWERED REVERSE OSMOSIS DESALINATION UNITS-DESIGN, START UP, OPERATING EXPERIENCE-,
GKSS - Forschungszentrum Geesthacht G.m.b.H., Geesthacht-Tesperhude (Germany, F.R.)
G. Petersen, S. Fries, J. Mohn, and A. Muller.
Desalination, Vol 39, Nos 1/2/3, p 125-135, December 1981, 8 Fig, 1 Tab, 5 Ref, (2nd Vol. Proc.

of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: Desalination, Desalination plants, Reverse osmosis, Solar energy, Wind, Plate modules, Photovoltaic solar generator, Wind converter, Mexico, Suderoog Island, Germany.

To demonstrate the operation of reverse osmosis (RO) units with GKSS plate modules coupled with unconventional energy supply systems, two projects are presently carried out by the GKSS research center applying a photovoltaic solar generator and a wind energy converter for a site in the Northern part of Mexico and a small island at the German coast of the North Sea, respectively. The solar generator with a designed peak power of 2.5 kW is developed by AEG and powers a RO unit for the desalination of brackish well water. The plant has been installed in Concepcion del Oro, Zacatecas, in spring 1980 and has been operated by the Mexican company DIGAASES in cooperation with AEG and GKSS since May 1980. The second project is a 6- kW wind-energy converter supplying 3 RO modules with a total membrane area of 30 sq m. After comprehensive component tests at the GKSS research center at Geesthacht the plant was installed at the very small island of Suderoog at the German coast of the North Sea. Test operation was started in December 1980.

WASTE HEAT POWERED REVERSE OSMOSIS PLANTS,
Envirogenics Systems Co., El Monte, CA.
R. A. Tidball, and R. Kadaj.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 137-145, 3 Fig, 4 Tab, 2 Ref, (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Reverse osmosis, Biphase, Turbine, *Waste heat.

The purchased power required for operation of reverse osmosis (RO) systems can be greatly reduced or sometimes eliminated by reclaiming waste heat from diesel engines, gas turbines, flare gases, etc. This can be accomplished by using a biphase turbine to convert low level waste heat to shaft horsepower. The system can be designed to use waste heat from existing installations or to reduce the size of the generating equipment in new supplies. The biphase conservation turbine is driven by a two phase stream generated by flashing a superheated liquid through a nozzle to the turbine. The turbine can be directly coupled to a pump shaft, to an electrical generator or to a combination of the two. Performance of the turbine is discussed. The waste heat recovery turbine and a hydraulic turbine to recover energy from the high pressure concentrated brine can be combined into one system. The design is described of a seawater RO system using waste heat from an existing diesel generating unit. The system is designed to produce 750 cmd of 400-ppm water at an energy consumption of approximately 2.5 KWH of purchased power p/cu m. A discussion of available desalination capacity at various quantities and temperature levels of the waste heat is presented. A comparison of water costs obtained using this system and a conventional electrical drive is presented.

USABILITY OF LOW TEMPERATURE WASTE HEAT FOR SEA WATER DESALINATION,
Nord-Aqua Oy, Espoo (Finland).
R. Saari.
In: Desalination, Vol 39, Nos 1/2/3, December 1981, p 147-158, 9 Fig, 3 Ref. (2nd Vol Proc of Int Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, *Multieffect distillation, Seawater, *Waste heat.

Waste heat energy that is cooled away from a process appears at two very different temperature levels. The waste heat that is 50C warmer than the ambience, can be utilized by a multieffect-distillation process, and it is competitive to utilize it at least as thoroughly as the first-rate energy. At low temperatures, less than 20C above the ambient temperature, waste heat can be technically, and economically utilized, if the temperature difference is 7 to 15C, depending on the pumping energy cost.

OCEAN THERMAL ENERGY AND DESALINATION,
Alsthom-Atlantique, Grenoble (France). Neyrtec Div.
M. Rey, and F. Lauro.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 159-168, 5 Fig, 3 Tab, (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Ocean circulation, *Thermal power, *Energy conversion, *Temperature gradient.

In 1981, the French physicist d'Arsonval was the first to suggest the harnessing of the temperature difference between the warm surface layers and cold deep layers of tropical oceans. Since then, several attempts have been made to convert this undepletable supply of thermal potential energy into mechanical energy and, later, into electricity. In recent years, various countries including France have launched thermal energy conversion (OTEC) programs. Tropical regions with useful temperature differences often lack both conventional energy resources and potable water. In such regions, OTEC plants could be used with advantage for the simultaneous production of power and desalinated seawater. An original seawater distillation scheme using surface water and the cold reject stream from an OTEC cycle is discussed. Power not required for distillation may be exported outside the plant. The combined distillation and OTEC scheme is compared with conventional desalination plant producing both potable water and electricity. The OTEC scheme appears highly flexible and shows considerable economic promise.

EXPERIMENTS WITH DESALINATION OF ARABIAN GULF WATER,
M. El Salem.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 261-271, 6 Fig, 5 Tab, (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination processes, Membranes, *Reverse osmosis, Plate-and-frame, Thin films, *Composite membranes.

With the 'plate-and-frame' reverse osmosis system and a new thin film composite membrane it has been possible to desalt very salty water (43.000 ppm). A minimum of pretreatment has been necessary because the membranes are very resistant to pH and temperature, and the flow rate in the plate-and-frame modules is very high. The raw water is pumped directly to the multi-media filter, followed by a 25-micron cartridge filter. The growth of algae and bacteria is prevented by irradiation with UV-light. After the pretreatment the water is pumped into the modules and desalted. The economy of the process is good because of the high capacity of the membranes and the small degree of pretreatment.

Descriptors: *Desalination, Desalination plants, Distillation, *Flash distillation.

The effects were investigated of different operating and geometrical parameters on the flashing efficiency of water in a single stage flashing chamber. This chamber used a submerged rectangular orifice as flow control area. Experiments were performed to investigate the effects of flow rate, liquid level in the flashing chamber, liquid inlet temperature, and flashing range on the flashing efficiency under various design conditions. These comprise flow with baffle placed in the flashing chamber and wire meshes placed at the orifice to increase the turbulence level. The efficiency increased with the increase of the turbulence levels, flashing range, and liquid inlet temperature; the efficiency deceased with the increase of the flow rate and liquid level in the flashing chamber. The application of numerical procedure to predict flow pattern and heat transfer in the flashing chamber is introduced as a powerful design tool.

Desalination, Vol 39, Nos 1/2/3, December 1981, p 295 (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Groundwater, *Recharge, Isotope studies, Fayoum area, Egypt, Chemical analysis, Quaroom lake, Nile Valley, Cairo.

Group 3A—Saline Water Conversion

The Fayoum area is located to the west of the Nile Valley, southwest of Cairo. It is a depression of an area of about 2000 sq km oriented in NW/SE direction. The Fayoum Province is connected to the Nile Valley by an old channel. To the northwest of the Fayoum area lies Quaroon lake with a salinity of about 4%, which is close to that of seawater. As a result of geological structure of this area, about 7 springs are scattered in the area. The area gets its main fresh water supplies from Bahr Yousel Canal, however, a considerable quantity of water is supplied from groundwater recharged from the cracked and cavernous limestone. Groundwater is recharged from the Nile and not from Bahr Yousef. Local groundwater is regarded as a source for some water inflow to Bahr Yousef. The recharge pattern of the groundwater is given. The contribution of the salty water of Quaroom lake is discussed.

Zagazig Univ. (Egypt).
B. Mabrook, F. Sweilm, and R. El Sheikh Shoheib.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 297 (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: Subsurface water, *Groundwater, Aquifers, *Hydrology, Khartoum, *Sudan, Nubia sandstone, El Gazira foundation, Egypt.

The study of the groundwater resources in Khartoum Province and the possibilities of their development have led to the question of hydrochemical variation with subsurface water origin. A combination between hydrogeological conditions with chemical and isotopic analyses is given for evaluation of the water resources. The principal water bearing formation are Nubia sandstone, El Gazira formation, and the alluvial wadi deposits. The storage capacity of the different aquifers as well as annual storage change are estimated. The hydrochemical composition of the aquifers reflects the continental NaHCO sub 3 and Na sub 2 SO sub 4 water types. Subsurface water is recharged from pluvial periods and present running water. Local groundwater is regarded as a source for some water inflow to running water.

R. Manjarrez.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 335 (Abstract only) (2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, *Organizations, Political aspects, Mexico.

For the last 20 years Mexico has been gradually installing desalination plants for a diversity of purposes. Within the Mexican government desalination activities have been promoted by two agencies. The first has been responsible for desalination in service of better quality water for power generation while in the alternate the emphasis has been in brackish and saline water conversion for community potable and consumer related water supplies. The private sector has in most instances also relied on the government agencies for satisfying of industrial needs but not to the exclusion of private industry desalination plant construction. The effectiveness of the approach utilized by the government agencies active in the field is reviewed along with the possible and potential impact of the use of desalination by the private sector.

Distillation, Brines, *Pumps, Materials
Corrosion, *Multistage flash distillation.

The different steps involved in design and
of brine recirculation pumps are reviewed p
larly regarding reliability against wear and
sion. The running conditions of the pumps d
on the nature of the fluid pumped and its te
ture. The large range in capacity and low
head enable the pumps to endure difficult
tions. The development program for a co
pumping range for multistage flash (MSF)
nation plants includes: design and model tes
the hydraulic part, research platform tes
checking and increase of hydraulic perfor
especially for cavitation, design of a pump
type for 6000 cu m/d MSF unit (1.6 mgd
endurance test for loop simulation in the las
of MSF. In 1980 there were 4 runs of 1000
with dismantling and examination of all parts
end of each run. Pumps were designed for
industrial plants of 10,000 and 20,000 cu m
and 6 mgd).

THE APPLICATION OF PELTON TYPE IMPULSE TURBINES FOR ENERGY RECOVERY ON SEA WATER REVERSE OSMOSIS SYSTEMS,
Hayward-Tyler Pump Co., Burlington, VT.
D. J. Woodcock, and I. M. White.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 447-458, 7 Fig. (Comprising 2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination apparatus, Reverse osmosis, Seawater, Energy recovery, Costs, *Turbines.

Impulse turbine technology is well-established and readily adaptable to energy recovery systems for seawater reverse osmosis. The broad operating range and standardized package approach allows a high level of design engineering availability and flexibility for standard plant sizes from 30,000 GPD to 3 MGPD. The high-efficiency, simple design and operating requirements of impulse turbines, makes them particularly attractive for energy recovery systems. Reductions of approximately 45% in required energy can result in significant energy savings and improve the competitive price for fresh water produced from seawater reverse osmosis. As the world requirement for fresh water grows, combined with the demand for conservation of oil and the increase in energy cost, the attraction toward impulse turbine energy recovery systems will similarly grow over a wider range of economic conditions and plant sizes.

AN INTEGRATED SELF SUFFICIENT MULTIPURPOSE PLANT FOR SEAWATER DESALINATION,
Kraftwerk Union A.G., Erlangen (Germany, F.R.).
K. Kuenstle, and G. Brunner.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 459-474, 5 Fig, 1 Tab, 2 Ref. (Comrising 2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, Desalination plants, Seawater, *Multistage flash/vertical tube evaporator, Drinking water, Chemical potential.

A multipurpose plant is described, which produces drinking water and chemicals from seawater. The most important part of the plant consists in a combined multistage flash/vertical tube evaporator, which operates on a high economy ratio and enables also a high concentration of the brine. These two facts are due to a special treatment of the evaporator feedwater by chemical agents produced from the concentrated brine. A surplus of these chemicals can be sold. The energy supply of the complex is assured by an adequate power station, which provides process steam and electricity at such a ratio as to minimize fuel cost.

EDUCATION AND TRAINING IN DESALINATION AROUND THE WORLD,
Fairleigh Dickinson Univ., Teaneck, NJ.
R. Bakish.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 477-482, 4 Ref. (Comprising 2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, *Education, *Training, Desalination plants.

The need for education and training remains as great as ten years ago, and in principle all that is needed is a change of attitude. The problem then, as it is now, is the fact that those who need the trained personnel must realize that the need is real. Once this is accomplished, they must add the cost of training to the plant costs and be prepared to cover them. It appears that perhaps the most difficult task is that of educating plant management to the need for trained operators.

HANDLING OF FUZZY DECISIONS IN THE ENGINEERING MANAGEMENT OF LARGE DESALINATION PLANTS,
Riyadh Univ. (Saudi Arabia). Coll. of Engineering.
A-R. F. Abdul-Fattah.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 489-490 (Abstract only) (Comprising 2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: Desalination, *Desalination plants, *Management planning, Fuzzy set theory.

Engineering managers of large desalination projects often face several alternate strategies, the choice among which is rather unclear due to the lack of specific statistics to favor one choice over the others. Usually, the manager eliminates some options in a preliminary screening process, thus ending with a limited but viable alternative, each of which has its own merits. Fuzzy set theory provides a practicable tool in cases of management decisions under uncertainty where the factors affecting the decision are imprecise in nature. Fuzzy decision-making utilizes the set theory to provide ranges representing subjective judgements in absence of precise quantitative measures. The approach has been formalized in an interactive computer code which can be easily used by managers without the need for familiarization with the theoretical foundations of set theory.

A TAILORED PROCESS FOR REMINERALIZATION AND POTABILIZATION OF DESALINATED WATER,
Italconsult, Rome (Italy).
E. Gabbrielli.
Desalination, Vol 39, Nos 1/2/3, December 1981, p 503-520, 1 Fig, 4 Tab, 20 Ref. (Comprising 2nd Vol. Proc. of Int. Congress on Desalination and Water Reuse, Manama, Nov. 29-Dec. 3, 1981).

Descriptors: *Desalination, *Water treatment, *Potable water, Drinking water, Mineralization, Remineralization, Potabilization.

Economic analysis of feasible remineralization and potabilization policies for desalination water emphasizes the desirability of a process producing fresh water which is of high quality in every respect (health, stability, palatability, etc.). In fact

the cost of such a process is only a fraction of that required for actual desalination (7.5% in the reported case). A complete remineralization and potabilization process is discussed particularly suited for desalinated water with relatively low residual TDS. The process is based on the use of natural carbonate rocks and CO sub 2, and enables all the basic stability parameters of the fresh water produced to be adjusted to the desired values, even in the presence of relatively large quantities of chlorides (100-200 ppm) and fairly high final TDS (400-500 ppm); at the same time purchase of large quantities of manufactured salts is avoided. The critical steps in designing such a plant are outlined and a comparative assessment is made of the capital and running costs of the suggested process and of another using manufactured salts such as CaCl sub 2 and NaHCO sub 3. The remineralization and potabilization unit is increasingly becoming a specialized part of the desalting plant, the design of which calls for specific know-how.

3B. Water Yield Improvement

WATER INFORMATION FOR NORTHWESTERN MISSOURI--A PLANNING DOCUMENT,
Geological Survey, Rolla, MO. Water Resources Div.
J. Skelton, E. J. Harvey, and D. E. Miller.
USGS Water Resources Investigation, 1982. 58 p, 7 Fig, 12 Tab, 22 Ref.

Descriptors: Water resources planning, *Potential water supply, *Glacial drift, *Alluvium, *Low flow, *Missouri, Population growth rates, Water quality, Water use, Gaging stations, Missouri River, *Streamflow statistics, Coal gasification, Pennsylvanian bedrock.

Water supplies are limited in much of northwestern Missouri, and water-resources data are also limited. The report presents a summary of hydrologic data and an evaluation of areas where future hydrologic investigations would be most useful. The largest and most dependable surface-water supplies that can be obtained without storage from tributary streams are from the lower Grand, Nodaway, and Chariton Rivers. The sources of ground water in order of quantities available are the Missouri River alluvium, glacial drift, tributary stream alluvium, and Pennsylvanian bedrock. Irrigation and industry are concentrated along the Missouri River where alluvial ground water is abundant. (USGS)

EVALUATING THE EFFECTIVENESS OF PROMOTING RESIDENTIAL WATER CONSERVATION THROUGH EXHIBITS,
Virginia Water Resources Research Center, Blacksburg
K. P. Sevebeck, and W. R. Walker.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-140565, Price codes: A10 in paper copy, A01 in microfiche. Completion Report, August 1983. 254 p, 30 Ref, 18 Append. OWRT C-10048-C and T(No 1448)(1), 14-34-0001-1448.

Descriptors: *Water conservation, *Conservation, *Domestic water conservation, *Education, Computer programs, *Exhibits, Computers, Domestic water, Water quality, Water quantity, Water use, Technology transfer.

This report describes how the Virginia Water Resources Research Center designed, constructed, implemented, and evaluated an exhibit program on residential water conservation. The report contains detailed information on the components of five exhibits and includes specific information on fabricating audio-visual displays, visitor participatory units, computer programs, and written educational materials to promote residential water conservation. Appendices list sources for equipment; describe computer programs; present construction drawings and exhibit photographs; and give sample evaluation and interview questionnaires, promotional materials, and three publications. Evaluation of the exhibit program showed that an exhibit is an effective medium for promoting residential water conservation and for changing citizen attitudes about water resources.

REPORT OF THE RIVER MASTER OF THE DELAWARE RIVER FOR THE PERIOD DECEMBER 1, 1980-NOVEMBER 30, 1981,
Geological Survey, Milford, PA. Water Resources Div.
F. T. Schaefer, and R. E. Fish.
Available from the OFSS, USGS, Lakewood, CO 80225, Price: $14.25 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-341, 1982. 115 p, 9 Fig, 20 Tab.

Descriptors: *Delaware River, *Diversion release, Water management, *Drought, Water quality, Water supply, Salt water intrusion, Reservoir yield, *Regulation, Supply, Interbasin transfers.

Water supply conditions at the beginning of the year were marginal in marked contrast to those for the preceeding nine years. Discharge of the Delaware River at Montague, New Jersey, was only 72% of median as compared to 68% in excess of median the previous year. In December, with reservoir storage again declining, further reductions in both diversions and releases were imposed. With consent of all the parties, reductions were effected on December 20 limiting New York City diversions to 560 mgd, New Jersey to 65 mgd, and the required discharge at Montague was targeted at 1550 cfs. To conserve supplies, additional reductions were imposed in January when the Delaware River basin Commission formally declared a drought. New York City's limitations was set at 520 mgd and that for New Jersey at 62 mgd. Montague flows were targeted between 1100 cfs, depending upon the location of the salt front in the estuary. Water quality of the Delaware River and Estuary was monitored on a continuous basis at eight sites for most of the year and on a monthly basis at ten sites to accurately locate the salt front. Highest concentrations observed at the Benjamin Franklin Bridge site was 133 mg/l (milligram per liter) on February 2. (USGS)

4. WATER QUANTITY MANAGEMENT AND CONTROL

4B. Groundwater Management

GEOHYDROLOGIC RECONNAISSANCE OF DRAINAGE WELLS IN FLORIDA--AN INTERIM REPORT,
Geological Survey, Tallahassee, FL. Water Resources Div.
J. O. Kimrey, and L. D. Fayard.
Available from the OFSS, USGS Lakewood, CO 80225, Price: $8.00 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-860, 1982. 14 Fig, 6 Tab, 41 Ref.

Descriptors: *Drainage wells, *Injection wells, *Artificial recharge, *Groundwater pollution, Underground storage, Carbonate aquifers, *Florida, Statewide reconnaissance.

Drainage wells are used to inject surface water directly into an aquifer, or shallow groundwater directly into a deeper aquifer, primarily by gravity. Such wells in Florida may be grouped into two broad types: (1) Surface-water injection wells, and (2) interaquifer connector wells. Surface-water injection wells are commonly used to supplement drainage for urban areas in karst terranes of central and north Florida. Data are available for 2 wells in the Ocala, Live Oak, and Orlando areas to allow comparison of the quality of water injected from these Floridan aquifer drainage wells with allowable contaminant levels. Comparison indicates that maximum contaminant levels for turbidity, color, and iron, manganese, and lead concentrations are equaled or exceeded in some drainage well samples, and relatively high counts for coliform bacteria are present in most wells. Interaquifer connector wells are used in the phosphate mining areas of Polk and Hillsborough County to drain mining operations and recharge the Floridan aquifer. Water-quality data available from interconnector wells indicate that samples from most of these wells exceed standards values for iron concentration and turbidity. One well yielded a highly mineralized water, and samples from 6 of the 12 wells exceed standards values for gross beta concentrations. (USGS)
W84-00865

LAND SUBSIDENCE IN THE SAN JOAQUIN VALLEY, CALIFORNIA, AS OF 1980,
Geological Survey, Sacramento, CA. Water Resources Div.
R. L. Ireland, J. F. Poland, and F. S. Riley.
Available from the OFSS, USGS Lakewood, CO 80225, Price: $18.25 in paper copy, $4.50 in microfiche. USGS Open-File Report 82-370, June 1984. 129 p, 70 Fig, 6 Tab, 55 Ref.

Descriptors: *Subsidence, *Extensometers, *Groundwater, *Confined aquifer, *Unconfined aquifer, *California, San Joaquin Valley, Los Banos-Kettleman City Area, Tulare-Wasco Area, Arvin-Maricopa Area.

Land subsidence due to ground-water overdraft in the San Joaquin Valley began in the mid-1920's and continued at alarming rates until surface water imported through major canals and aqueducts in the 1950's and late 1960's. In areas where surface water replaced withdrawal of ground-water, water levels in the confined system rose sharply and subsidence slowed. In the late 1960's and early 1970's water levels in wells recovered to levels of the 1940's and 1950's throughout most of the northern and southern parts of the Valley, in response to the importation of surface water through the California aqueduct. During the 1976-77 drought, data collected at water-level and extensometer sites showed the effect of heavy demand on the groundwater resevoir. With the 'water of compaction' gone, artesian head declined 10 to 20 times as much as during the first cycle of long-term drawdown that ended in the late 1960's. In the 1978-79 water levels recovered to or above the 1976 pre-drought levels. The report suggests continued monitoring of land subsidence in the San Joaquin Valley. (USGS)

esources development, Irrigation, Finan-
cts, *Aquifer recharge, Aquifers, Ground-
mping, Artificial recharge, Groundwater
ent, *Nebraska.

dology was sought for estimating ground
charge benefits in irrigation use areas, and
hodology was used to estimate ground
charge benefits for selected situations.
jectives were addressed using a Nebraska
presented, the methodology separates re-
enefits into two components: pumping
ings and aquifer extension benefits. Simpli-
edures designed for use by state and fed-
r planning agencies are presented for each
benefits component. Experience indicates
required data, time, and computer re-
or the model were within the range which
ermit use of the model for first round,
ssance level studies as well as for more
ensive analyses. Results of recharge bene-
ations indicate that benefits in irrigation
probably range from less than $2.00 to
0 an acre foot. A comparison to published
recharge costs concludes that single pur-
arge programs to augment water supplies
tion are certainly economically unfeasible.
, the analysis indicates that the benefits of
are probably substantial enough to merit
sideration as part of appropriate multipur-
er projects. (Baker-FRC)

**GINEERING ECONOMIC ANALYSIS
IFICIAL RECHARGE IN A CONJUNC-
TIVE IRRIGATION PLAN IN THE COLUMBIA BASIN PROJECT, WASHINGTON,**
Geological Survey, Tacoma, WA. Water Resources Div.
M. R. Karlinger, and A. J. Hansen, Jr.
Available from the National Technical Information Service, Springfield, VA 22161 as PB83-196022, Price codes: A03 in paper copy, A01 in microfiche. USGS Open-File Report 81-67, 1983. 28 p, 6 Fig, 7 Tab, 6 Ref.

Descriptors: *Artificial recharge, *Irrigation practices, Irrigation wells, Surface irrigation, Economic feasibility, *Columbia Basin Project, *Washington, *Conjunctive use.

An appraisal-level engineering economic cost analysis was performed for two primary types of irrigation systems in a portion of the Columbia Basin Project- a surface-water irrigation system in which water is supplied via canals and laterals, and a system in which surface water is brought to recharging wells and eventually to farms using the transmissive properties of the aquifer and pumping. At 1979 electric power rates, the artificial-recharge irrigation scheme is a viable alternative to surface-distributed irrigation systems, but as electric rates increase, its viability decreases. At three times the 1979 rate, the recharge scheme is uneconomical. (USGS)

NUMERICAL SIMULATION OF GROUNDWATER FLOW IN THE LOWER SATUS CREEK BASIN, YAKIMA INDIAN RESERVATION, WASHINGTON,
Geological Survey, Tacoma, WA. Water Resources Div.
E. A. Prych.
USGS Water Resources Investigations Report 82-4065, 1983. 78 p, 30 Fig, 17 Tab, 16 Ref.

Descriptors: *Groundwater, *Computer models, Waterlogging, Groundwater basins, Groundwater management, Canal seepage, Drawdown, *Geohydrology, Satus Creek, Lower Satus Creek basin, *Washington, Yakima Indian Reservation.

A multilayer numerical model of steady-state ground-water flow in lower Satus Creek basin was constructed, calibrated using time-averaged data, and used to estimate the long-term effects of proposed irrigation-water management plans on ground-water levels in the area. Model computations showed that irrigation of new lands in the Satus uplands would raise ground-water levels in lower Satus Creek basin and thereby increase the size of the waterlogged areas. The model also demonstrated that pumping water from wells, reducing the amount of irrigation water used in the lowlands, and stopping leakage from Satus No. 2 and 3 Pump Canals were all effective methods to alleviate present waterlogging in some parts of the basin and to counteract some of the anticipated ground-water-level rises that would be caused by irrigating the uplands. The proposed changes in water use affected model-computed ground-water levels most in the eastern part of the basin between Satus No. 2 and No. 3 Pump Canals. The effects on ground-water levels in the western part of the basin between Satus Creek and Satus No. 2 Pump Canal were smaller. (USGS)

4C. Effects On Water Of Man's Non-Water Activities

MODEL MODIFICATIONS FOR SIMULATION OF FLOW THROUGH STRATIFIED ROCKS IN EASTERN OHIO,
Geological Survey, Columbus, OH. Water Resources Div.
J. O. Helgesen, S. P. Larson, and A. C. Razem.
USGS Water-Resources Investigations 82-4019, 1982. 109 p, 6 Fig, 6 Ref.

Descriptors: *Computer models, Perched groundwater, *Groundwater flow, Perched springs, Surface-groundwater relations, *Ohio, Computer programs, Three dimensional flow.

A quasi three-dimensional groundwater flow model is being used as part of a study to determine impacts of coal-strip mining on local hydrologic systems. Modifications to the model were necessary to simulate local hydrologic conditions properly. Perched water tables required that the method of calculating vertical flow rate be changed. A head-dependent spring-discharge function and a head-dependent stream aquifer-interchange function were added to the program. Modifications were also made to allow recharge from precipitation to any layer. The modified program, data deck instructions, and sample input and output are presented. (USGS)

Descriptors: *Mine drainage, *Environmental effects, *Simulation analysis, Hydrologic models, Hydrologic budget, Cumulative impacts, Hydrologic consequences.

Techniques were developed to assess the probable cumulative impacts of anticipated surface mining upon the hydrology of and area. An activity profile of cumulative drainage area versus river miles downstream from the surface mining site is constructed that shows major water uses, flood prone areas, and stream classifications. From the summary shown by the activity profile, an impact matrix is used as a checklist for the importance of the impacts under categories such as water supply, flood prone areas, water contact recreation, etc. Based on the categories checked on the impact matrix, a simple, less accurate model or a more comprehensive and accurate one can be used to quantify the impacts. Quantified impacts are then displayed on an impact profile showing the percentage change in a hydrologic characteristic versus distance downstream of the surface mining site. The simple model for quantification considers only dilution from tributary areas during critical periods whereas the comprehensive model routes flows and quality of water continuously through the year and considers, in addition to dilution, instream processes such as settling, biological uptake, and chemical reactions. EFFECTS OF URBANIZATION ON THE MAGNITUDE AND FREQUENCY OF FLOODS ON SMALL STREAMS IN TENNESSEE-BASIC DATA REPORT NO. 2,
Geological Survey, Nashville, TN. Water Resources Div.
C. H. Robbins.
Available from the OFSS, USGS, Lakewood, CO 80225; Price: $3.50 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-911, 1982. 25 p, 1 Fig.

Descriptors: *Floods, *Small watersheds, *Hydrologic data, Peak discharge, Gaging stations, Flood peaks, Basin characteristics, *Tennessee.

Peak stages, discharges, and rainfall recorded at 22 gaging stations on streams draining small (less than 25 mi super 2) urbanized basins across Tennessee

are presented. The gaged basins are in 17 different municipalities with populations ranging between 5,000 and 100,000. The report gives a description of each gaged site along with a data sheet on which peak stages, discharges, and corresponding rainfall are listed. The description gives the station location, type of gage, basin characteristics, and general remarks. (USGS)

Descriptors: *Floods, *Flood profiles, High water mark, Step-backwater routing, Flow through bridges, *Tennessee, Spencer.

The Tennessee Department of Transportation has constructed a new bridge and approaches on State Route 30 over Cane Creek near Spencer, Tennessee. The old bridge and its approaches were fairly low, permitting considerable flow over the road during high floods. The new bridge and its approaches are considerably higher, causing different flow conditions at the site. Analysis of the effects of the new bridge, as compared to the old bridge, on floods of the magnitude of the May 27, 1973, flood is presented. The May 27, 1973, flood was greater than a 100-year flood. Analysis of the 50- and 100-year floods for the new bridge are also presented. Results of the study indicate that the new construction will increase the water-surface elevation for a flood equal to the May 27, 1973, flood by approximately 1 foot upstream from bridge. (USGS)

POTENTIAL EFFECTS OF SURFACE COAL MINING ON THE HYDROLOGY OF THE COOK CREEK AREA, ASHLAND COAL FIELD, SOUTHEASTERN MONTANA,
Geological Survey, Helena, MT. Water Resources Div.
M. R. Cannon.
Available from the USGS, OFSS, Federal Center, Lakewood, CO 80225, Paper copy $8.0, Microfiche $4.50. USGS Open-File Report 82-681, August 1982. 30 p, 7 Fig, 3 Tab, 28 Ref.

Descriptors: Hydrology, *Coal mines, *Reclamation, *Water quality, *Montana, Cook Creek, Powder River Basin, *Hydrologic data, *Shallow aquifers, Groundwater.

The Cook Creek area of the Ashland coal field contains large reserves of Federally owned coal that have been identified for potential lease sale. A hydrologic study has been conducted in the potential lease area to describe existing hydrologic systems and to assess potential impacts of surface coal mining on local water resources. Hydrogeologic data collected from wells, springs, and drill holes indicate that shallow aquifers exist within the Tongue River Member of the Fort Union Formation (Paleocene age) and within valley alluvium (Pleistocene and Holocene age). Shallow aquifers within the Tonge River Member include coal beds, clinker, and lenses of sandstone and siltstone. The Knobloch coal bed, a principal shallow aquifer used for livestock watering in the area, averages about 55 feet in thickness and is completely saturated throughout most of its extent. Coarse alluvial deposits are the most productive aquifers and are a major source of stock water in the Cook Creek basin. Surface-water resources are limited to the upstream reach part of Cook Creek, which flows intermittently. The downstream reach part of Cook Creek, plus all other small drainages that originate in the study area, are ephemeral. Mining of the Knoblock and Sawyer coal beds would remove two alluvial springs, one bedrock spring, and two wells, which are all used for watering of livestock. The potentiometric surface within the Knobloch coal aquifer and the alluvial aquifer in the downstream part of the Cook Creek basin would be lowered during mining. Lowered water levels in these aquifers might substantially affect water levels in five wells outside the mine boundary. After mining, the alluvial aquifer downgradient from the mine area might show a long-term degradation in water quality as a result of leaching of soluble salts from overburden materials used to backfill mine pits. Although mining would alter the existing hydrologic systems and remove several springs and shallow wells, alternative groundwater supplies are available that could be developed to replace those lost by mining. PREMINING HYDROLOGY OF THE LIGNITE AREA IN SOUTHEASTERN DE SOTO PARISH, LOUISIANA,
Geological Survey, Baton Rouge, LA. Water Resources Div.
J. L. Snider.
Louisiana Department of Transportation and Development, Baton Rouge, Water Resources Technical Report No 29, 1982. 40 p, 11 Fig, 4 Tab, 28 Ref.

Descriptors: *Dewatering, *Groundwater level, *Impaired water quality, *Saline-water intrusion, Sediment basins, *Strip-mine wastes, *Suspended sediments, Coal mining, Groundwater movement, Groundwater recharge, Intermittent streams, Transmissivity, Unconfined aquifers, Water-level fluctuations, Aquifer restoration, De Soto Parish, *Louisiana, Chemard Lake lignite, Dolet Hills aquifer, Low-sulfur lignite, Fault zone, Sand-clay mixing, Sand-grain packing.

Surface mining of the Chemard Lake lignite will affect the ground- and surface-water hydrology in southeastern De Soto Parish, Louisiana. The mining will involve dewatering and removing the Dolet Hills aquifer, which overlies the lignite. This will interrupt local recharge to the aquifer and cause water-level decline near the mined area. After an area is mined the pit will be filled with spoil. The sand from the Dolet Hills aquifer may be implaced without being mixed with clay from the overburden. Under these conditions, the transmissivity of the replaced spoil may be higher initially than that of the original aquifer because of loose packing. In the event that sand and clay in the spoil are intermixed, water movement could be retarded. The major effects on water in streams draining disturbed land would be increased mineralization and increase in sediment load. Mining operators can minimize these problems by storing and treating mine drainage in sediment ponds. (USGS)

IMPACT OF CHANGES IN LAND USE ON THE GROUND-WATER SYSTEM IN THE SEQUIM-DUNGENESS PENINSULA, CLALLAM COUNTY, WASHINGTON,
Geological Survey, Tacoma, WA. Water Resources Div.
B. W. Drost.
USGS Water-Resources Investigations Report 83-4094, 1983. 61 p, 29 Fig, 9 Tab, 22 Ref.

Descriptors: Hydrologic budget, *Groundwater recharge, *Aquifer characteristics, Saline water encroachment, Low flow, *Water quality, Clallam County, *Washington, Dungeness River.

A digital-computer model was developed to simulate three-dimensional ground-water flow in aquifers underlying the Sequim-Dungeness peninsula, Clallam County, Washington. Analysis using the model shows that leakage from irrigation ditches is the area's most important source of ground-water recharge. Termination of the irrigation system would lead to lower heads throughout the ground-water system. After 10-20 years of no irrigation, the water-table aquifer would have average drawdowns of about 20 feet and some areas would become completely unsaturated. Several hundred wells could be in danger of going dry. If irrigation were terminated, leakage from the Dungeness River would become the major source of ground-water recharge. As of June 1980, ground-water quality has apparently not been affected in the study area by the use
domestic sewage-disposal systems. The
trate-plus-nitrite (as N) concentration in
table aquifer was 0.25 milligrams per lite
maximum concentration was 2.5 millig
liter. (USGS)

QUALITY ASSURANCE PRACTICES FOR THE CHEMICAL AND PHYSICAL ANALYSES OF WATER AND FLUVIAL SEDIMENTS,
Geological Survey, Lakewood, CO.
L. C. Friedman, and D. E. Erdmann.
Available from the Eastern Distribution Br. USGS, 604 S. Pickett St. Alexandria, VA 22304. USGS Techniques of Water-Resources Investigations, Book 5, Laboratory Analysis, Chapter A6, 1982. 181 p, 35 Fig, 40 Tab, 71 Ref.

Descriptors: *Quality control, Statistical methods, Evaluation, *Analytical techniques, *Instrumentation, Test procedures, Documentation, Data collection, Measurement, *Water analysis, Reliability, Water quality control, Data storage and retrieval, Chemical analysis, Biological properties, Materials testing, Charts, Sampling.

This manual contains practices used by the U.S. Geological Survey to assure the quality of analytical data for water, fluvial sediment, and aquatic organisms. These practices are directed primarily toward personnel making water-quality measurement. Some detail specific quality control techniques, others document quality assurance procedures being used by the Central Laboratories System of the U.S. Geological Survey and still others describe various statistical techniques and give examples of their use in evaluating and assuring the quality of analytical data. The practices are arranged into eight sections: Analytical Methods Development Procedures; Standard Quantitative Analysis Techniques; Instrumental Techniques; Reference Material; Laboratory Quality Control; Quality Assurance Monitoring; Documentation, Summary, and Evaluation of Data; and Materials Evaluation. Each section is preceded by a brief description of the material covered. Similarly within each section, each practice is preceded by a description of its application or scope. (USGS)

ANALYSIS OF WATER SAMPLES FOR TOXIC VOLATILE ORGANIC COMPOUNDS: STATE OF THE ART METHODS AND STRATEGIES FOR SAMPLING,
New Mexico State Univ., Las Cruces. Dept. of Chemistry
G. A. Eiceman.
Proceedings of Twenty-eighth Annual New Mexico Conference, 'Water Quality in New Mexico,' April 5-6, 1983. WRRI Report No 169, New Mexico Water Resources Research Institute, Las Cruces, June 1983. p 170-185, 6 Fig, 12 Ref.

Descriptors: *Volatile solids, *Chemical wastes, *Vapor pressure, *Gas chromatography, *Toxicity, *Hazardous wastes, *Poisons, *Surveys, Chromatography, Water sampling, Testing procedures, Water resources institutes, Water quality standards, Rivers.

Rapid development of advanced analytical methods for determining toxic volatile organic compounds (VOC) in water coincided with their discovery in river and drinking water, however, evidence of interest in this subject dates from the early 1950s. Methods of analysis of water for VOC were refined throughout the 1970s so that today rapid analysis of aqueous samples for complex mixtures of VOC at parts per billion concentration ranges are relatively rapid and inexpensive. There were three major technical limitations relative to VOC in water in the mid-1970s. They were: (1) the volatile and, thus, transient nature of VOC during sample handling, (2) an aqueous matrix which may be considered deleterious to expensive analytical instrumentation, and (3) the presence of VOC at microgram per liter concentration levels in sometimes complex mixtures. Vapor pressure studies show that not all small molecules have identical vapor pressure, and small changes in molecular structure, such as the presence of polar bonds (O-H in ethanol versus nonpolar O-CH2CH3 in ether) lead to startling differences in vapor pressure. Because VOC are often found in mixtures rather than isolated species, and because molecule-specific detectors do not exist, gas chromatographic methods are ideal to physically separate individual component in a sample before measurement using a detector. A model for loss of VOC from the Tennessee River was developed and tested, which can be used to make decisions on the best placement of sampling sites. (Garrison-Omniplan)

QUALITY-ASSURANCE DATA FOR ROUTINE WATER ANALYSIS IN THE LABORATORIES OF THE U.S. GEOLOGICAL SURVEY: 1981 ANNUAL REPORT,
Geological Survey, Denver, CO. Water Resources Div.
D. B. Pearst, and N. Thomas.
USGS Water-Resources Investigations Report 83-4090, 1983. 112 p, 184 Fig, 5 Tab, 7 Ref.

Descriptors: Alkalinity, *Chemical analysis, Chlorophyll a, Dissolved solids, *Heavy metals, Nitrogen compounds, Phosphorus, Specific conductivity, Statistics, *Trace elements, *Trace metals, *Water analysis, *Quality-assurance data.

The U.S. Geological Survey maintains a quality-assurance program based on the analysis of reference samples for its two water-analysis laboratories located in Atlanta, Georgia and Denver, Colorado. Reference containing inorganic constituents are prepared at the U.S. Geological Survey's Ocala, Florida, office and disguised as routine samples, and sent daily to each laboratory through other U.S. Geological Survey offices. The results are permanently stored in the National Water Data Storage and Retrieval System (WATSTORE), the U.S. Geological Survey's data base for all water data. These data are analyzed statistically for precision and bias. The results of these statistical analyses are presented for data collected during the 1981 calendar year. In addition, one sample containing known concentrations of trihalomethanes and samples containing unknown concentrations of chlorophyll a were analyzed in both laboratories, and these results also are presented. (USGS)

SPECIFIC IDENTIFICATION OF ORGANIC POLLUTANTS IN HAW RIVER WATER USING GAS CHROMATOGRAPHY/MASS SPECTROMETRY,
North Carolina Univ. at Chapel Hill. Dept. of Environmental Sciences and Engineering.
A. M. Dietrich, D. S. Millington, and R. F. Christman.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-140524, Price codes: A07 in paper copy, A01 in microfiche. Water Resources Research Institute Report No 206, August 1983, Raleigh, NC. 130 p, 20 Fig, 23 Tab, 3 Ref, 1 Append. A-127-NC(1), 14-34-0001-2135.

Descriptors: *Water pollution, *Rivers, *Organic compounds, *Pollutant identification, *Gas chromatography, *Mass spectrometry, Water quality, Water sampling, Organic pesticides, Phosphorus compounds, Industrial wastewater, Municipal wastewater, Wastewater disposal, Sample preparation, Resins, Mass spectra, Trace levels.

This study investigated organic pollution in the Haw River of North Carolina utilizing current advanced methods for extraction and concentration of aqueous trace organic pollutants combined with identification by Gas Chromatography/Mass Spectrometry (GC/MS). During the one and one-half year study, fifty-two different trace organics were detected in water in samples taken from three sampling sites on the Haw River. The sampling site at the Town of Haw River, located in the industrialized Piedmont, contained the greatest number of trace organic compounds. The sampling site at Bynum, downstream from the Town of Haw River, contained fewer compounds and were frequently the same compounds as those identified at the Town of Haw River site. Water analyzed from Oak Ridge, located upstream from the Town of Haw River, contained the fewest trace organic

contaminants and these pollutants were chemically dissimilar to those found at the other two sites. A trace organic pollutant profile of the Haw River has emerged from this work. The fifty-two organic pollutants detected and identified were determined to be in low microgram/liter (ppb) concentrations, although they contained only three priority pollutants. This data should not be interpreted as a survey or monitoring study of organic composition of the Haw River, since few sampling sites were involved and the purpose was focused on evaluating analytical methodology.

RECONNAISSANCE FOR DETERMINING EFFECTS OF LAND USE AND SURFICIAL GEOLOGY ON CONCENTRATIONS OF SELECTED ELEMENTS ON STREAMBED MATERIALS FROM THE COAL MINING, REGION, SOUTHWESTERN INDIANA, OCTOBER 1979 TO MARCH 1980,
Geological Survey, Indianapolis, IN. Water Resources Div.
W. G. Wilber, and R. R. Boje.
USGS Water-Resources Investigations 82-4013, Nov. 1982. 39 p, 2 Fig, 6 Tab, 40 Ref.

Descriptors: *Bottom sediments, *Coal mining, *Heavy metals, *Indiana, *Land use, Particle size, *Statistical analysis, Streambeds, *Analysis of variance, Agricultural watersheds, Forest watersheds, Trace elements.

Streambed materials were collected in October 1979 from 69 watersheds in Southwest Indiana having predominantly forested, agricultural, reclaimed, and unreclaimed mined land use to determine whether concentrations of sorbed and acid-soluble metals and trace elements were affected by land use and surficial geology. Analysis of variance indicated that 10% or more of the total variation in aluminum, arsenic, cobalt, iron, nickel, selenium, and zinc concentrations on streambed materials was accounted for by differences in land use. Concentrations of aluminum, cobalt, iron, nickel, selenium, and zinc on streambed materials smaller than 0.062-millimeter from mined watersheds were significantly greater than the concentrations of these elements on streambed materials from agricultural and forested watersheds. The greater concentrations of these elements on streambed materials are due to (1) their concentrations in mine drainage and their subsequent absorption and (or) copecipitation with the oxides and hydroxides of aluminum and iron and (2) their concentrations in coal and pyritic material in streambed materials. EFFECT OF URBANIZATION ON THE WATER RESOURCES OF WARMINSTER TOWNSHIP, BUCKS COUNTY, PENNSYLVANIA,
Geological Survey, Harrisburg, PA. Water Resources Div.
R. A. Sloto, and D. K. Davis.
USGS Water-Resources Investigations 82-4020, Jan. 1983. 72 p, 20 Fig, 16 Tab, 28 Ref.

Descriptors: *Urbanization, *Groundwater, *Organic solvents, *Water pollution sources, Lead, Trichloroethylene, Tetrachloroethylene, *Pennsylvania, Bucks County, Montgomery County.

Rapid suburban development occurred in Warminster Township after World War II, resulting in a large population dependent on groundwater. A stream-gain-and-loss study showed that losses from Little Neshaminy Creek were equal to 57% of the water pumped from wells near the stream. Groundwater infiltration to sewers was about 850 million gallons in 1979, and about 250 million gallons in 1980. In a year with average precipitation, (45 inches), evapotranspiration is about 24 inches and recharge about 11 inches. As much as 1.1 million gallons per day of additional water may be attached by drilling and pumping wells in areas not now affected by groundwater pumping. Contamination by volatile organic compounds has caused the water from some wells to be unsuitable for public supply. The median concentration of lead in groundwater, 17 micrograms per liter, is above the national median concentration. The concentration of most dissolved constituents increased in water from seven wells sampled at the onset of urbanization in 1953 and 1956 and again in 1979. Effluent from sewage treatment plants has degraded the chemical quality of stream at low flow. (USGS)

STATUS OF GROUND WATER QUALITY IN LOGAN TOWNSHIP, GLOUCESTER COUNTY,
New Jersey Dept. of Environmental Protection, Trenton. Div. of Water Resources.
L. R. Miller, H. Kachroo, S. Andres, and R. Riccio.
Report, February 1982. 158 p, 6 Fig, 4 Tab, 9 Ref, 1 Append.

Descriptors: *Water quality, *Industrial wastes, *Pollutants, *Organic wastes, *Groundwater pollution, *Water pollution sources, Confined aquifers, Groundwater movement, Water sampling, Chemical analysis, Well water, Test wells.

The New Jersey Division of Water Resources (DWR) evaluated the ground water impacts from four possible industrial sources of contamination in Logan Township. DWR sampled 89 wells. The investigation detected ground water contamination at the Monsanto Chemical Company site, but no off-site contamination can be attributed to Monsanto's operation. Ground water contamination has been present since 1972 at Rollins Environmental Services, a hazardous waste treatment facility. Pollutants have been detected to a depth of approximately 70 feet. However, the samples showed that no private residential wells had been contaminated as a result of Rollins' waste disposal practices. Monitoring wells in the vicinity of Bridgeport Rental and Oil Services and Chemical Leaman Tank Lines detected extremely high concentrations of organic pollutants in both ground water and in a deep well between those two industrial sites. Serious contamination of the shallow, intermediate, and deep ground water zones has been detected at the Chemical Leaman site. Public water supply wells had no detectable levels of organic contaminants. Lead levels in one of the public wells was slightly elevated (53 parts per billion in March 1981) and will be monitored, although none of the industries is considered responsible for this condition. DWR recommended a program for future sampling of ground water in the affected areas. (Fazio-Omniplan)

SURVEILLANCE AND ANALYSIS:
UNK CREEK AND LITTLE BEAR
WATERSHEDS,
The State Univ., New Brunswick, NJ.
sources Research Inst.
le, Jr., A. W. McIntosh, and J. V.

Water Quality Planning Program Report, April 1980, Mercer County, NJ, 85 p, 19 Fig, 12 Tab, 25 Ref, 5 Append.

Descriptors: *Stream pollution, *Water quality, *Biological samples, Watershed management, Water pollution sources, Fish, Ecosystems, Benthic fauna, Macroinvertebrates, Heavy metals, Pollutants, Industrial wastes, Organic wastes, Coliforms, Storm runoff, *New Jersey, Shabakunk Creek watershed, Little Bear Brook watershed.

This report evaluates conditions of water pollution and environmental degradation in the watersheds of Shabakunk Creek and Little Bear Brook, New Jersey. The work was undertaken to determine probable causes of observed adverse conditions and, given sufficient information, to determine preventive or remedial programs. The watershed of the West Branch Shabakunk Creek is highly urbanized and environmentally impacted. The Main Branch Shabakunk and Little Bear Brooks are less seriously polluted although Little Bear may periodically have received discharges of hazardous organic wastes. In both watersheds, biological survey and analysis complemented the data obtained by water quality sampling. Although no known point sources enter the Shabakunk Creek, sections of the creek below developed areas are in poor biological condition, with only a few small fish and pollution-tolerant groups of benthic macroinvertebrates present. Water quality analyses indicated that fecal coliform counts often exceed the New Jersey standard of 200 per 100 ml for FW-2 waters. Scrapings from riffles below the most developed areas contained the highest heavy metal concentrations. The presence of storm water runoff and illegal discharges remains a serious problem. Little Bear Brook apparently receives sewage contamination from residential areas. Mercer County will develop guidelines for stream surveillance and analysis studies for use by other areas designing similar efforts. (Fazio-Omniplan) W84-00801

MERCER COUNTY STORMWATER TOXICS MANAGEMENT PROJECT: DELAWARE AND RARITAN CANAL CONDUIT SPECIAL STUDY, TRENTON, NEW JERSEY.
Mercer County Planning Div., Trenton, NJ.
New Jersey Department of Environmental Protection and Mercer County Water Quality Planning Program, Final Report, 1982. 115 p, 11 Fig, 28 Tab, 48 Ref, 3 Append.

Descriptors: Water quality, *Water quality management, *Storm runoff, *Storm sewers, *Urban runoff, *Chemical analysis, *Pollutants, Canals, Drainage effects, Drainage water, Biochemical oxygen demand, Hydrocarbons, Heavy metals, Polychlorinated biphenyls, Pesticides, Biological samples, Benthic fauna, Enforcement, *New Jersey, Trenton, Mercer County.

A two year study of stormwater runoff in the Trenton, New Jersey area determined the nature and extent of toxic substances entering the Delaware and Raritan Canal, which is extensively used for boating, fishing, swimming, and drinking water supply. Earlier studies had detected toxic pollutants, such as heavy metals, polychlorinated biphenyls, and pesticides in Canal sediments, which were suspected to be entering the Canal through storm sewer discharges. Physical, chemical, and biological sampling and analyses substantiated the need to properly manage the quality of stormwater runoff entering valued water resources. The methodology was based on Mercer County's earlier 'stream surveillance' studies. The study found concentrations of biological oxygen demand, total hydrocarbons, and heavy metals in urban stormwater runoff similar to those reported in the literature. Cadmium, copper, lead and zinc were the predominant heavy metals found. Highway runoff contained lower levels of contamination than urban stormwater runoff. Stormwater runoff from urban residential as well as industrial and commercial areas contained high levels of contamination. Biological surveys identified the greatest effects of pollution nearest the inlet and outlet of the Trenton Conduit. Concentrations of existing contaminants in sediments appeared to be highly localized. Several monitoring and inspection programs are recommended to track the quality of reclining waters, drinking waters and pollutants. (Fazio-Omniplan) W84-00802

WATER-QUALITY ASSESSMENT OF THE AMERICAN RIVER, CALIFORNIA,
Geological Survey, Sacramento, CA. Water Resources Div.
M. V. Shulters.
USGS Open-File Report 82-763, December 1982. 66 p, 40 Fig, 11 Tab, 36 Ref.

Descriptors: *Water quality, Water quality standards, *Water use, *California, *American River, *Time trend analyses, Specific conductance, Hardness, Alkalinity, *Urban runoff.

Based on an analysis of water-quality data from more than 168 sites, the American River was found to be of overall good quality and suitable for all beneficial uses specified by the State of California, even though its natural condition has been altered by man's activities in the basin. Time trend analyses indicate an increase in specific conductance (dissolved solids), hardness, and alkalinity over the past 20 years in the lower American River near Sacramento downstream from treated effluent and urban runoff sources. Most violations of specific water quality objectives for the basin have occurred in this segment. Water-quality conditions in the segment are expected to improve in 1982 when sewage treatment facility discharges will be discontinued. Potential water-quality problems in the upper American River basin could result from recreational overuse, improper land-use or poorly managed mining operations. Recreational overuse and increased urban runoff are the principal threats to water quality in the lower American River. Proposed monitoring activities include low-flow investigations on the lower American to measure diurnal variations in water-quality characteristics and studies in the uppper basin to determine the impact of increasing recreation and development as well as the effects of mine discharge. Report SWP-9, June 1979. 121 p, 18 Fig, 41 Tab, 6 Append.

Descriptors: *River basins, *Acid mine drainage, *Stream pollution, *Acidic water, *Thermal pollution, *Aquatic habitats, *Water quality, Streams, Rivers, Water policy, Groundwater pollution, Flood control, Flood damage, *Pennsylvania, Upper West Branch Susquehanna River.

Most of the northern half of Subbasin 8 in Pennsylvania is in state ownership, and is primarily state forest land; however, it also includes state game lands and state Parks. The subbasin is described in one of 23 reports being published as a result of initial investigations and studies conducted in connection with the State Water Plan of the Commonwealth. Mining operations have impacted negatively on the land and water resources here. Whereas the upper basin has been left relatively undeveloped and preserved, the lower basin has been scarred and left with acid streams unfit for biologic habitat. As a result, the general water quality of Subbasin 8 is poor. Many of the problems originate in tributaries and headwaters to the West Branch Susquehanna River. Limestone in Watershed B neutralizes the acidity upstream, leaving high concentrations of total dissolved solids from calcium and magnesium in the limestone and from the iron, manganese and sulfates in the coal. Thermal pollution from the Shawville electric power generating plant would be a problem were it not that aquatic life has already been eliminated by the high acidity in the river. There have been incidents of groundwater pollution; better land management practices are needed to reduce such incidents in the future. There are only 295,000 tons of sediment leaving the basin each year, one of the smallest erosion rates in the state. Flood damages are common because of the mountainous terrain. (Garrison-Omniplan)

THE PUERCO RIVER: MUDDY ISSUES RAISED BY A MINE WATER DOMINATED EPHEMERAL STREAM,
New Mexico Health and Environment Dept., Santa Fe. Environmental Improvement Div.
B. Gallaher.
Proceedings of Twenty-eighth Annual New Mexico Conference, 'Water Quality in New Mexico,' April 5-6, 1983. WRRI Report No 169, New Mexico Water Resources Research Institute, Las Cruces, June 1983. p 60-68, 9 Fig, 1 Tab, 2 Ref.

Descriptors: *Ephemeral streams, Intermittent streams, *Radioactive wastes, *Uranium, *Dewatering, *Water quality standards, Stream pollution, *State jurisdiction, Legal aspects, Water policy, Water resources institutes, Hazardous materials, *New Mexico, Puerco River.

Increased urbanization and industrialization has caused an increase in the disposal of wastewater in ephemeral watercourses. Because there is minimal in-stream dilution of wastewater, the impacts on ground water may be more severe than from a discharge to a perennial stream. Since 1968, dewatering of underground uranium mines in the Church Rock Uranium Mining District has caused perennial flow in the Puerco River. During 1982, the discharge rate was nearly 5,000 gallons of mine dewatering effluent per minute. Although the quality of water discharged from the mines is regulated, the quality of water in the Puerco River itself is subject to little regulatory control in New Mexico. Because of its ephemeral nature, the Puerco River has no designated uses. Therefore, there are no specific stream standards applicable to that channel except the narrative general standards applicable to all surface waters of the state. Arizona has determined that its segment of the Puerco River should be protected for aquatic life, wildlife, irrigation and livestock. Eighteen numerical standards have been developed for metals, radionuclides and nutrients. A recent report by the Environmental Improvement Division noted that the Puerco River contains levels of radioactivity and certain toxic metals that approach or exceed standards or guidelines designed to protect the health of people, livestock and agricultural crops. Data suggest that no level of improvement in effluent quality would render the river totally suitable for these uses. (Garrison-Omniplan)

HYDROCARBON FUELS IN GROUND WATER--INCREASED AWARENESS AND CONCERN IN NEW MEXICO,
New Mexico Health and Environment Dept., Santa Fe. Environmental Improvement Div.
D. Jercinovic.
Proceedings of Twenty-eighth Annual New Mexico Conference, 'Water Quality in New Mexico,' April 5-6, 1983. WRRI Report No 169, New Mexico Water Resources Research Institute, Las Cruces, June 1983. p 35-47, 1 Fig, 1 Tab, 7 Ref.

Descriptors: *Aromatic hydrocarbons, Pollutants, *Hazardous materials, *Chemical wastes, *Industrial wastes, *Data collection, *Surveys, *Water pollution effects, Lubricants, Oil, Petroleum products, State jurisdiction, *New Mexico.

The New Mexico Environmental Improvement Division (EID) has become increasingly aware of the waste contamination problems associated with the leakage and surface disposal of hydrocarbon fuels, including refined petroleum products such as gasoline, kerosene, gas oil (diesel fuel), fuel oils and lubricating oils. The aromatic hydrocarbons commonly found in gasoline include compounds such as benzene, toluene and xylenes, all of which are extremely soluble in ground water. Sources of contamination are the six active gasoline refineries in New Mexico, which are responsible for transportation of hydrocarbon fuels, storage and handling, and disposal. In June 1982, the EID began to inventory all known or suspected cases of hydrocarbon fuel contamination of ground water as a first step in evaluating statewide impacts. Of the 78 incidents recorded, more than 32% were associated with underground leakage of hydrocarbon fuels from commercial retail outlets. Property damage and aquifer restoration costs have climbed as high as $10 million from a single leaking underground gasoline tank. Preliminary suggestions include periodic tank testing of all underground fuel storage tanks, requiring hydrocarbon fuels or hydrocarbon fuel-contaminated water to be discharged into lined evaporation ponds, prompt reporting of all losses to local or central EID offices, and accurate daily inventories of all stored fuels. evious study, estimated phosphorus (P)
from septic systems to lakes in the Puget
gion were found to be correlated with the
of old homes around the lakes. In the
udy, we assessed the movement of septic-
in seasonally perched ground water near
e, a typical glacial-till lake in the region.
und water occurs in soils overlying less
e glacial till, which is prevalent around
e and many other lakes in the area. Water
were taken from 15 shallow (<1.5 meters)
talled 10-50 meters downgradient from
tic systems 20 to 40 years old. The equiv-
metric fraction of each sample consisting
ted effluent was estimated from chloride
ation. Using Monte Carlo analysis to ac-
the various sources of uncertainty, we
at, though movement of diluted septic effluent to the lake was common, transport of more than 1% of effluent P through the soil was probable ($p > or = 0.5$) for only 4 of 26 samples, was transport of more than 10% of effluent P probable. The highest probabilities of P movement were associated with two samples from a well that was downgradient from a drainfield located at the base of a hillslope depression where perched ground water concentrates and remains for extended periods. All evidence considered, most P loading to Pine Lake from septic systems appears to come from only a few older systems located in areas where perched ground-water flow and associated saturated soil conditions predominate for extended periods during the winter season. GROUNDWATER QUALITY IN NEW JERSEY--AN INVESTIGATION OF TOXIC CONTAMINANTS,
New Jersey Dept. of Environmental Protection, Trenton. Office of Cancer and Toxic Substances Research.
R. K. Tucker.
Report, March 1981. 60 p, 10 Fig, 8 Tab, 101 Ref, 1 Append.

Descriptors: *Chemical wastes, *Pesticide toxicity, *Groundwater pollution, *Groundwater contamination, *Chemical analysis, Water pollution, Hazardous materials, Water quality, Recharge, Poisons, Metals, *New Jersey.

Fifty chemicals in three groups--halogenated volatile organics, chlorinated pesticides and related compounds, and metals--were searched in well water samples throughout New Jersey. A total of 1,118 samples were taken from 670 sites. Although this is a significant sample size, it is a small portion of the more than 16,000 potable wells in the state. One or more of eight volatile organic compounds were found at concentrations above ten parts per billion in 16.6% of the wells tested. Five of the eight chemicals (carbon tetrachloride, chloroform, dichloroethane, tetrachloroethylene, and trichloroethylene) have been established via animal tests as capable of causing cancer and three others (trichloroethane, and the di-and tri-chlorobenzenes) are chemically similar to known carcinogens, but no reliable evidence exists to prove that they are carcinogenic. In 3.1% of the wells in the study, concentrations of one or more of these eight chemicals exceeded one hundred parts per billion, a clearly unacceptable level. It is hypothesized that low level concentrations of volatile organics may occur in wells subject to widespread contamination by a variety of mechanisms, including aerial transport and recharge from surface waters. In contrast, higher levels of contamination occur in a population of wells subject to direct and relatively nearby discharge of pollutants into the ground. Chlorinated pesticides and related compounds, when detected in this study, were usually at very low concentrations. (Garrison-Omniplan)

WATER-QUALITY ASSESSMENT OF THE MERCED RIVER, CALIFORNIA,
Geological Survey, Sacramento, CA. Water Resources Div.
S. K. Sorenson.
USGS Open-File Report 82-450, November, 1982. 46 p, 21 Fig, 4 Tab, 18 Ref.

Descriptors: *Water quality, *Water quality standards, *Water use, *California, Merced River, Lake McClure, McSwain Reservoir.

The Merced River and its major tributaries have been subject of water-quality and water-quantity studies by local, State, and Federal agencies since before 1900. Data have been compiled and analyzed, and even though water-quality problems exist in the basin, the water generally is of good quality for most of the beneficial uses defined by the California State Water Resources Control Board. Water-quality objectives for dissolved oxygen, pesticides, and pH were violated in some parts of the basin. The most likely cause of the dissolved-oxygen and pesticide violations is the return of agricultural irrigation water to the river in the lower 30 miles of the river. Violations of pH objectives occurred only in the upper drainage and were likely due to naturally occurring, poorly buffered water. Water quality is currently being monitored at three stations in the basin by California Department of Water Resources, at one station by the U.S. Geological Survey, and at several sites by the National Park Service. Modifications to the current water-quality monitoring program are proposed to gain further information on dissolved-oxygen fluctuations and pesticide concentrations in the lower river and to investigate nutrient input to Lake McClue. W84-00924

RECONNAISSANCE OF STORMWATER-RUNOFF WATER QUALITY OF THE BIG PINEY CREEK SEGMENT OF THE CEDAR-PINEY WATERSHED, YELL COUNTY, ARKANSAS,
Geological Survey, Little Rock, AR. Water Resources Div.
J. C. Peterson.
Available from the OFSS, USGS Lakewood CO 80225, Price: $2.75 in paper copy, $3.50 in microfiche. USGS Open-File Report 82-761, May 1982. 14 p, 1 Tab, 12 Ref.

Descriptors: *Water quality, *Small watersheds, *Storm runoff, *Nutrients, Coliforms, Streptococcus, Iron, Manganese, Sediments discharge, *Arkansas, Watershed reconnaisance.

A reconnaissance of the Big Piney Creek watershed was made between June 1981 and January 1982 to assess the water quality of selected streams in the watershed. Streamflow was measured and water samples were collected three times at each of three sites during the study. All samples were collected during periods of stormwater runoff. The water was soft (7 to 20 milligrams per liter of hardness as calcium carbonate) and dissolved-solids concentrations ranged from 36 to 74 milligrams per liter. Suspended-sediment concentrations ranged from 7 to 144 milligrams per liter. The 5-day biochemical oxygen-demands, total-nitrogen concentrations and total-phosphorus concentrations ranged from 1.5 to 6.8 milligrams per liter, 0.54 to 5.8 milligrams per liter, and 0.03 to 0.56 milligram per liter, respectively. Fecal-coliform bacteria were present in large enough concentrations at two of the sites (340 to 490 colonies per 100 milliliters and 1,200 to 6,000 colonies per 100 milliliters) to indicate that the U.S. Environmental Protection Agency criterion for bathing waters and the Arkansas water-quality standard may be exceeded at times. Total-iron concentrations greater than 1,000 micrograms per liter (the U.S. Environmental Protection Agency criterion for protection of freshwater aquatic life) were detected at least once at all sites. (USGS)

NITRATE LOSS FROM AGRICULTURAL DRAINAGE WATERS: IMPLICATIONS FOR NONPOINT SOURCE CONTROL,
North Carolina State Univ. at Raleigh. Dept. of Soil Science.
T. C. Jacobs, and J. W. Gilliam.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-140581, Price codes: A11 in paper copy, A01 in microfiche. North Carolina Water Resources Research Institute Completion Report Nc 209, September 1983. 222 p, 50 Fig, 27 Tab, 34 Ref, 12 Append. OWRT B-129-NC(1), 14-34-0001-0238.

Descriptors: *Denitrification, *Drainage effects, *Buffers, *Agricultural watersheds, *Nitrogen losses, *Nitrogen movement, Nitrates, Soil water movement, Riparian vegetation, Water pollution sources, Fertilizers, Drainage water, Subsurface drainage, Surface runoff, *North Carolina, Coastal plain.

The amount and fate of nitrogen moving from agricultural fields in two watersheds of the North Carolina Coastal Plain were examined. The possible sinks for this nitrogen and their effects on stream concentration were determined. At the Beaverdam Creek watershed where well- and moder-

ately well-drained soils dominate the agricultural fields, nitrogen readily moved from the fields. However, between most fields and the natural streams, there were buffer strips with heavy riparian vegetation. These buffer areas with poorly drained soils resulted in significant losses of nitrate before the water reached the stream. Very narrow buffer strips were effective for this removal and these strips normally line streams on the Middle Coastal Plain. In soils with subsurface drainage entering ditches via tile lines or subsurface flow, the losses of nitrogen to surface waters were much greater. In watersheds of the Upper and Middle Coastal Plain in-stream losses of nitrogen are not sufficient to reduce heavy loading by nonpoint sources. The floodplains, which have a high capacity to reduce nitrate, usually flood in the winter when temperatures are too low for extensive losses. At the Creeping Swamp watershed in the Lower Coastal Plain, a dense clay layer below the surface horizons reduces subsurface drainage losses of water and nitrogen to very low levels.

This study has determined the principal hydrochemical processes in the headwaters of the Fort River near Amherst, Massachusetts and has initiated a detailed analysis of groundwater in Cadwell Creek, a tributary of the Quabbin Reservoir. Incoming precipitation has an average pH of 4.06 and total dissolved solids of approximately 3.5 ppm, although seasonal variations do occur. Over 99% of the incoming H+ ions are being neutralized in the watershed, primarily by cation exchange and silicate weathering reactions. This produces stream water with a pH between 5.2 and 6.0, and total dissolved solids of 25 to 30 ppm. Major cations are leaving the watershed at a rate six times greater than they are entering. Ca super 2+ is removed fastest, followed in order by Mg super 2+, Na+, and K+. The total chemical denudation rate including SiO sub 2 and SO sub 4 super 2- is 6130 kg/km super 2/yr (about 1.5 times greater than that calculated for Hubbard Brook, New Hampshire). Surficial geology controls the specific composition of streamwater in individual subwatersheds. Drainage basins underlain by till are more effective at neutralizing precipitation acidity than those with abundant stratified drift and/or shallow bedrock. A similar relationship is evident in the composition of groundwater in Cadwell Creek. Research is continuing on Cadwell Creek wells.

TRANSPORT MODELING OF AN AGRICULTURAL HERBICIDE, A LABORATORY SIMULATION,
Kansas State Univ., Manhattan. Dept. of Civil Engineering.
E. C. McCall, Jr., D. D. Lane, and A. D. Parr.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-140623, Price codes: A03 in paper copy, A01 in microfiche. Water Resources Research Institute Contribution No 240, August 1983. 25 p, 11 Fig, 3 Tab, 23 Ref. OWRT A-106-KAN(1), 14-34-0001-2118.

Descriptors: *Herbicide runoff, *Laboratory simulation, *Atrazine, Soil flume, *Agricultural runoff, Clay loam, Rainfall, Transport modeling, Mass transport.

A one-dimensional flow, laboratory soil flume was used to simulate atrazine loss from a field during rainfall runoff events. Liquid atrazine was surface applied at a rate of 3360 g/ha to a Pawnee clay loam soil. Rainfall events of 1.3 cm/hr and 2.5 cm/hr of one hour durations were applied to the soil flume one day after atrazine application. The rainfall was simulated by overland flow only. The flume was 'placed' in upper, middle and lower locations in a 300 m long, 9% slope field. The soil was saturated and allowed to drain to field capacity before the rainfall event. The flume bottom was impervious to prevent infiltration. For this worst case condition, 90% of the atrazine lost was in the runoff water and the majority of the atrazine loss occurred within twenty minutes of the beginning of the runoff events. Thirty-five percent of the atrazine applied was transported from the field for both the 1.3 and 2.5 cm runoff events. No change in the mass transported by the two different intensity runoff events appears to be due to a limit placed on atrazine availability for runoff by the atrazine rate of desorption and dissolution. The desorption, dissolution process appears to be very slow, i. e., much greater than one hour, and thus the antecedent moisture conditions appear to place a finite limit on the atrazine which is available for runoff during a single event.

SITE STUDIES OF DETERMINE THE EXTENT AND POTENTIAL IMPACT OF HERBICIDE CONTAMINATION IN KANSAS WATERS,
Kansas State Univ., Manhattan. Dept. of Systematics and Ecology.
F. deNoyelles, Jr., and W. D. Kettle.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-140631, Price codes: A03 in paper copy, A01 in microfiche. Water Resources Research Institute Contribution No 239, September 1983. 37 p, 10 Fig, 8 Tab, 71 Ref, 2 Append. 0WRT A-104-KAN(1), 14-34-0001-2118.

Descriptors: *Herbicides, *Toxicant resistance, *Photosynthesis inhibitors, *Phytoplankton, *Macrophytes, Site studies, Aquatic habitats, Atrazine, Cyanazine, Propazine, Matribuzin, Simazine, Experimental ponds, Tailwater pits, Fish ponds, *Kansas.

The triazine herbicides have accounted for nearly one third of the total herbicide usage in Kansas in recent years. It is well known that these herbicides are entering aquatic habitats in Kansas and throughout the Midwest, yet little is known of their effects on the freshwater organisms residing there. This study was undertaken to accumulate data on triazine herbicide concentrations in State waters and to determine the biological impact of the triazines on phytoplankton and macrophyte communities at those sites. To develop baseline data on the biological effects of triazine herbicides, experimental ponds were treated with different levels of atrazine herbicide under highly controlled situations. Atrazine was chosen to represent the triazines because of its physiological effects on a wide variety of terrestrial and aquatic plants and because it is the single most heavily used pesticide in the United States. In the treated experimental ponds, communities of phytoplankton quickly developed which were more resistant to atrazine. Macrophytic vegetation was significantly inhibited in treated ponds. The next phase of the study involved sampling numerous aquatic habitats throughout the State to (1) analyze the concentrations of triazine herbicides (atrazine, cyanazine, metribuzin, and simazine) and to (2) determine if the macrophyte and phytoplankton communities at these sites had been altered by exposure to triazine herbicides. Triazines were detected at many sites and many of those sites were also found to contain phytoplankton communities possessing a degree of resistance to atrazine. Reductions in macrophyte communities were noted in those waters receiving direct runoff from agricultural fields.

Samples of sediment from the Housatonic Rive Connecticut and Massachusetts indicate that PC have accumulated predominantly in impoun reaches of the river where sediment accumula is greatest. Distribution of PCBs within the poundments is controlled by sediment particle s greatest PCB concentrations are associated w fine-grained sediment. Study results indicate t an estimated total of 22,200 pounds of PCBs contained in the river sediments, 60% are in M sachusetts, predominantly in the Woods Pond a and 40% are in Connecticut. In Connecticut, ab 29% of the PCBs are in lake Lillinonah, 10% ar Lake Zoar, and the remaining 1% is distributed small amounts at other areas. The rate of transp of PCBs in the Housatonic River from Massac setts into Connecticut by suspended sediment estimated to be 250-500 pounds per year. (USG

The U.S. Geological Survey One-Dimensional Stream Water-Quality Model, QUAL II Stream Water-Quality Routing Model, the U.S. Army corps of Engineers Water Quality for River Reservoir Systems Model, and the M.I.T. Transient Water Quality Network were evaluated and compared using actual water-quality data collected by the U.S. Geological Survey. The field data were taken from steady-state studies of the Chattahoochee River in Georgia, the Willamette River in Oregon, and the Arkansas River in Colorado. The data used to evaluate the models covered a wide range of physical, chemical, and biological conditions. The Willamette River is a large sluggish stream, whereas the Arkansas River is a small dynamic stream. The Chattahoochee River is of moderate size. Each stream has unique water-quality characteristics that test a wide range of model options. (USGS)

CHLOROFORM CONTAMINATION IN PART OF THE ALLUVIAL AQUIFER, SOUTHWEST LOUISVILLE, KENTUCKY,
Geological Survey, Louisville, KY. Water Resources Div.
R. W. Davis, and E. W. Matthers.
USGS Water Supply Paper 2202, 1983. 25 p, 18 Fig, 2 Tab, 4 Ref.

Descriptors: Organic compounds, *Path of pollutants, *Pollutant identification, Soil contamination, Water pollution effects, *Water pollution sources, Groundwater movement, *Chloroform, *Carbon tetrachloride, Rising water levels, Adsorbtion, *Kentucky, Louisville.

A well in alluvium at Louisville, KY., has been yielding water with concentrations of chloroform as high as 34.80 mg/L since July 1975. A spill of 5,000 gallons of chloroform in 1970, 120 ft from the well, is probably the source. The chloroform is adsorbed in the unsaturated zone in the alluvium; the greatest concentrations are near the water table. Lesser amounts of carbon tetrachloride are found with the chloroform. Its source is unknown. The two contaminants were in the unsaturated alluvium until rising ground-water levels caused water to contact them and the water-chloroform mixture began moving down-gradient to the well. High river stages cause a seasonal cycle of water level rise; the raised ground water comes in contact with more chloroform and the chloroform concentration of the well water increases. No carbon tetrachloride has been observed in the well water. (USGS)

QUALITY OF WATER IN LUXAPALLILA CREEK AT COLUMBUS, MISSISSIPPI,
Geological Survey, Jackson, MS. Water Resources Div.
S. J. Kalkhoff.
USGS Open-File Report 82-373, 1982. 38 p, 9 Fig, 2 Tab, 11 Ref.

Descriptors: *Water quality, *Mississippi, Surface waters, Low flow, Metals, Luxapallila Creek, Columbus, Lowndes County.

The results of a water quality study of a short reach of Luxapallila Creek at Columbus, Mississippi, during September 9-12, 1979, indicate that the water is colored (60 units) and has a low dissolved solids content (44 mg/L). The dissolved oxygen concentration, temperature, and pH of the water in Luxapallila Creek changed a slightly downstream through the study reach. The mean specific conductance almost doubled and the five-day biochemical oxygen demand load increased over four times through the study reach. The fecal coliform to fecal streptococcus ration of 3 to 5 samples collected at the downstream site was greater than 4.0, strongly suggesting the presence of human waste. The concentrations of iron and manganese at the downstream site exceeded the U.S. Environmental Protection Agency's criteria for domestic water supplies. High concentrations of iron, manganese, and lead also were present in a bottom material sample at the downstream site. (USGS)

QUALITY OF WATER AND TIME OF TRAVEL IN BAKERS CREEK NEAR CLINTON, MISSISSIPPI,
Geological Survey, Jackson, MS. Water Resources Div.
S. J. Kalkhoff.
USGS Open-File Report 82-427, 1982. 37 p, 9 Fig, 2 Tab, 5 Ref.

Descriptors: *Water quality, *Mississippi, Surface waters, Low flow, Dissolved oxygen, Bakers Creek, Lindsey Creek, Clinton, Hinds County.

Although dissolved-oxygen concentrations remained below 5 milligrams per liter, the water quality in Bakers Creek improved in a 1.8 mile reach downstream of a (source of) wastewater outfall. The mean specific conductance decreased from 670 micromhos per centimeter to 306 micromhos per centimeter. The 5-day biochemical oxygen demand decreased from 19 to 2.8 milligrams per liter. The mean total nitrogen and phosphorus concentrations decreased from 10 to 7.1 milligrams per liter to 1.0 and 0.87 milligrams per liter, respectively. Maximum fecal coliform bacteria decreased from 7200 to 400 colonies per 100 milliliters. The concentrations of mercury (0.4 micrograms per liter), iron (3,400 micrograms per liter) and manganese (1,100 micrograms per liter) at the downstream site contained DDD (2.5 micrograms per kilogram), DDE (2.7 micrograms per kilogram), and DDT (.3 micrograms per kilogram). The average rate of travel through a 1.8-mile reach of Bakers Creek was 0.06 foot per second or 0.04 mile per hour. (USGS)
W84-01035

WATER QUALITY OF THE UPPER VERMILION RIVER, LOUISIANA, APRIL-AUGUST 1980,
Geological Survey, Baton Rouge, LA. Water Resources Div.
D. K. Demcheck, and H. L. Leone, Jr.
Louisiana Department of Transportation and Development, Baton Rouge, Water Resources Technical Report No 30, 1983. 37 p, 8 Fig, 9 Tab, 17 Ref.

Descriptors: Water quality, *Dissolved oxygen, Biochemical oxygen demand, *Conductivity, Trace metals, Ions, Pesticides, Enteric bacteria, *Productivity, Phytoplankton, Benthic fauna, Streamflow, *Louisiana, Upper Vermilion River, Lafayette, Water-quality differences, Bayou Teche.

Analyses of water-quality data collected during 1980 in a reach of the Vermilion River from its headwaters to a point 6 miles downstream from Lafayette, La., indicate that non-point runoff from the upper basin is a major factor in depressed dissolved-oxygen concentrations, high biochemical oxygen demand, and elevated fecal-bacteria concentrations. High flows masked the contributions of point and nonpoint sources in the Lafayette urban area. When flow lessened, waste inputs from the urban area degraded the water quality in the stagnant reach downstream from Lafayette, primarily through accumulations of nutrients, organic carbon, and biochemical oxygen demand. Changes in benthic macroinvertebrate populations and in algal dominance downstream from Lafayette suggest that discharges in the area have a detrimental impact on the already poor water quality of the Vermilion River during periods of low or zero flow. Samples were collected on an event basis from April through August 1980 and analyzed for inorganics, metals, pesticides and other organic compounds, nutrients, biochemical oxygen demand, fecal bacteria, phytoplankton, and benthic invertebrates. 5C. Effects Of Pollution

A SURVEY OF THE MUSSEL DENSITIES IN POOL 10 OF THE UPPER MISSISSIPPI RIVER,
Wisconsin Dept. of Natural Resources, Madison.
R. E. Duncan, and P. A. Thiel.
Technical Bulletin No 139, 1983. 14 p, 4 Fig, 2 Tab.

Descriptors: *Mussels, *Water pollution effects, *On-site data collections, *Shellfish, *Wildlife habitats, *Navigable rivers, River beds, Rivers, Water quality, Habitats, Reservoirs, Data collections, *Wisconsin, Mississippi River.

Impoundment, water quality, and other factors have had an impact on the mussel fauna of the Upper Mississippi River. The primary objective of this survey was to quantitatively define the diversity and relative density of the mussel community in Pool 10 of the river. Pool 10 extends from Lock and Dam No. 9 near Lynxville, Wisconsin, to Lock and Dam No. 10 at Guttenberg, Iowa, a total of 32.8 river miles. Of the 309 sites sampled, mussels were found at 224 sites, or 72%. The East Channel near Prairie du Chien, Wisconsin had the richest mussel fauna with an average density of 2.964 mussels per square foot; and only 6% of the sites were nonproductive. The lower end of Pool 10 had the lowest mussel density at 0.655 per square foot and the highest percentage of nonproductive sites, 38%. The mussel density in the main channel border was two times greater than in the main channel and backwater. A total of 12,150 live specimens representing 31 species of freshwater mussels were collected from Pool 10; an additional 7 species were represented only by dead specimens. Threeridge, Amblema plicata, was by far the most abundant mussel species, comprising 52.9% of the catch and having an average density of 0.832 per square foot. (Garrison-Omniplan)

The Monterey Wastewater Reclamation Study for Agriculture (MWRSA) has completed its first year of a five-year pilot effort to investigate and to demonstrate feasibility of food crop irrigation with reclaimed municipal effluent. The project comprises a 96-plot field trial for statistical comparison of three water treatments; an eight-hectare commercial scale farm for demonstration of water reclamation for growing lettuce, broccoli, cauliflower, celery, and artichokes; and aerosol study, a virus assay, market studies, and other ancillary investigations. First year results preliminarily indicate that the main hypothesis of the study will prove to be true, i.e. 'raw-eaten food crops irrigated with properly treated municipal wastewater effluent are safe for human consumption'.

5F. Water Treatment and Quality Alteration

REMOVING URANIUM FROM DRINKING WATER SUPPLIES: DEMONSTRATION OF SELECTED ION EXCHANGE AND CHEMICAL CLARIFICATION,
New Mexico State Univ., Las Cruces. Dept. of Chemical Engineering.
D. B. Wilson.
Proceedings of Twenty-eighth Annual New Mexico Conference, 'Water Quality in New Mexico,' April 5-6, 1983. WRRI Report No 169, New Mexico Water Resources Research Institute, Las Cruces, June 1983. p 193-206, 4 Fig, 6 Tab.

Descriptors: *Uranium, *Water quality standards, *Radioactive wastes, *Ion exchange, *Chemical coagulation, *Chemical flocculation, *Sedimentation, *Filtration, Flotation, Surveys, Water policy, Water resources institutes, Federal jurisdiction.

The proposed standard for uranium has been suggested as 10pCi/l (equivalent to 14.7 micrograms/l). Before establishing this standard, the U.S. Environmental Protection Agency must demonstrate available economical control technology for achieving such a level. This study is being conducted to demonstrate ion exchange and chemical clarification technology. Chemical clarification consists of coagulation, flocculation, and solid-liquid separation, such as sedimentation, flotation and/or filtration. While the mechanism of uranium removal via chemical clarification has not been proved conclusively, it most likely occurs through the adsorption of the uranyl ion complex by the coagulant precipitate. Conventional water treating systems which use chemical clarification employ either rapid-mix basins, flash-mix basins, or in-line mixers. Ion exchange is a separation process in which ions held by electrostatic forces to charged functional groups on the surface of an insoluble solid are replaced by ions of like charge in solution. Ion exchange has been used as a standard unit operation for the commercial recovery of uranium for many years. Graduate students in chemical and civil engineering are assembling the equipment for the chemical clarification evaluation experiments, and the ion exchange equipment is already operating on location. REMOVAL OF REFRACTORY ORGANICS FROM WATER BY AERATION. II. SOLVENT SUBLATION OF METHYLENE BLUE AND METHYL ORANGE,
Vanderbilt Univ., Nashville, TN. Dept. of Chemistry.
J. L. Womack, J. C. Lichter, and D. J. Wilson.
Separation Science and Technology, Vol 17, No 7, p 897-924, May, 1982. 17 Fig, 18 Ref.

Descriptors: *Separation techniques, *Organic compounds, *Surfactants, *Organic solvents, *Dyes, Theoretical analysis, Pollutant identification, Drinking water, Water analysis, Salts, Solvents, Water treatment.

In solvent sublation, a surface-active solute is transported from the aqueous phase to an overlying layer of a nonvolatile organic liquid on the air-water interfaces of bubbles rising through the solvent sublation cell. This technique has been suggested for removing dissolved substances from aqueous systems. The removal of the refractory organics methylene blue-sodium tetradecylsulfate and methyl orange-hexadecyl-trimethylammonium bromide from water to 2-octanol was carried out by solvent sublation. Three possible mechanisms were examined in the laboratory batch scale experiments. Potassium chloride, sodium nitrate and sodium biphosphate were tried as added salts. The colored species removed for each refractory compound is believed to consist of one ion of dye complexed with two of surfactant. The effects of mass transfer rate in the vicinity of the bubble-water interface were examined theoretically. The empirical time constant for mass transfer was related to the lowest eigenvalue of an appropriate diffusion problem. (Geiger-FRC)

POINT SOURCE WASTE LOAD ALLOCATION FOR THE TOWN OF RED RIVER,
New Mexico Health and Environment Dept., Santa Fe. Environmental Improvement Div.
D. F. Tague.
Proceedings of Twenty-eighth Annual New Mexico Conference, 'Water Quality in New Mexico,' April 5-6, 1983. New Mexico Water Resources Institute, Las Cruces, June 1983. p 12-21, 4 Fig, 3 Tab, 1 Ref.

Descriptors: *Waste load, Tertiary wastewater treatment, *Water quality standards, *Water quality criteria, *Surveys, *Water use, Nonpoint pollution sources, *Phosphorus, Stream discharge, Algal growth, Economic aspects, *Wastewater treatment, Secondary wastewater treatment, *New Mexico, Red River.

A point source waste load allocation for municipal discharge was required for the Red River in New Mexico when secondary treatment was not sufficient to meet water quality standards. First, the designated uses were identified and numeric or narrative criteria were determined that were sufficient to preserve the designated uses. A year-long stream and effluent sampling program was conducted. A series of 11 algal assay tests demonstrated that the Red River is a phosphorus-limited aquatic environment. Consequently, the river is exempt from the total inorganic nitrogen standard and a waste load allocation is not required for that constituent. The stream standard for total phosphorus (P) was exceeded on 15 of 21 sampling dates at the station below the treatment works. No other

violations of stream standards were observed at this station. At Station HRG-21, six miles above the town, where the natural quality of the river is represented, the average P concentration is 0.006 mg/liter. Cultural nonpoint sources in and above the town add phosphorus sufficient to raise the river concentration to 0.022 mg/liter, an increase of 3.67 times. Monthly phosphorus limitations were developed that take into account monthly low streamflow and seasonal variations in wastewater flow. The savings in costs of operation to the town of Red River that will result from wastewater treatment requirements for phosphorus and ammonia developed on a seasonal schedule was estimated at more than $200,000 per year. INDUSTRIAL WASTEWATER,
Texas Univ. at Austin. Dept. of Environmental Engineering.
G. A. Rohlich.
In: Proceedings of the National Water Conference, Water Quality and The Clean Water Act, Philadelphia, January 26 and 27, 1982. Academy of Natural Sciences, Philadelphia, July 1982. p 67-86, 8 Fig, 3 Tab, 9 Ref.

Descriptors: *Industrial wastes, *Manufacturing wastes, *Hazardous materials, *Industrial wastewater, *Water quality standards, *Water quality control, *Industrial plants, Poisins, Industrial production, Legal aspects, Water policy, Public policy, Municipal wastes.

Despite the vast amount of information available, technical solutions to the problem of industrial waste treatment become more complex in view of the inclusion of toxic pollutants in water quality standards and effluent limitations. Data on the performance of available treatment technology for removing many of the toxic constituents is limited or non-existent. Separation of waste streams at the source should be considered so that toxic materials can be segregated and handled independently. Some difficult issues to decide are what types of plants to use, the technical and economic sufficiencies of the facilities, and justifying why a particular type was selected in terms of social and legal constraints. Progress has been made in meeting the legal requirements of the National Pollutant Discharge Elimination System (NPDES). As of February 1980, nearly 59,000 NPDES permits were issued. Of these, 15,395 were to municipalities and 43,512 to non-municipal (mostly industrial) discharges. There has been a steady decline in the number of violations by non-municipal NPDES permit holders: 184 in 1977; 121 in 1978; and 64 in 1979. In the total pollution abatement category, total annual costs in 1979 are estimated to be $7.6 billion in 1979 and $11.5 billion in 1988. Future policies and legislation must place additional emphasis on 'prophylactic rather than therapeutic measures.' (Garrison-Omniplan)

MUNICIPAL WASTEWATER TREATMENT: 1970 AND TODAY,
Water Pollution Control Federation, Washington, DC.
C. F. Guarino.
In: Proceedings of the National Water Conference, Water Quality and The Clean Water Act, Philadelphia, January 26 and 27, 1982. The Academy of Natural Sciences, Philadelphia, July 1982. p 51-65.

Descriptors: *Municipal wastewater, *Industrial wastes, *Municipal wastes, *Legislation, *Federal jurisdiction, *Economic aspects, *Legal aspects, *Lake rehabilitation, Lake reclamation, Wastewater treatment, Water quality standards, Water quality control.

In 1970 the President's Council on Environmental Quality (CEQ) reported our nation needed to invest $10 billion in municipal water treatment and $3.3 billion in industrial control. During that year federal appropriations for research and development in the water pollution control field were increased to $60 million. Federal aid to state programs was set at $10 million. Two significant goals set by Congress were secondary treatment for municipal wastewater treatment authorities by July 1, 1977, and 'fishable, swimmable' waters wherever attainable by July 1, 1983. To date almost $32 billion has been appropriated for the program; $18 million has been spent. Yet the goals were not universally reached. Up to two-thirds of the treatment authorities in the country missed the 1977 deadline. By the end of 1979, heavy metal concentrations were reported by CEQ as the most widespread water quality problem, and 10,000 of some 37,000 public lakes were found to be in need of restoration or pollution control. On the other hand, some clean water successes have occurred in New Hampshire, New Jersey and Texas where fish have returned to formerly polluted waters. The Water Pollution Control Federation believes the EPA needs to devote more attention to questions of performance. Meanwhile, a revision to secondary treatment regulations should be made to allow case-by-case waivers of biochemical oxygen demand and suspended solids requirements or 85% removal criteria, based on water quality justifications. WHAT IS THE CONDITION OF OUR SURFACE WATER.,
Academy of Natural Sciences of Philadelphia, PA.
R. Patrick.
In: Proceedings of the National Water Conference, Water Quality and The Clean Water Act, Philadelphia, January 26 and 27, 1982. Academy of Natural Sciences, Philadelphia, July 1982. p 11-29, 11 Fig.

Descriptors: *Surface water, *Water quality control, *Water quality standards, *Stream improvement, *Stream pollution, Rivers, Water pollution, Legislation, Swimming, Wildlife habitats, Public policy, Water policy, Sediment load.

A single standard in pollution control cannot be applied throughout the United States because of variances in the natural and chemical characteristics of streams. Most of the streams in the southeastern United States have a dissolved oxygen content lower than 2 to 3 ppm. Likewise, the natural sediment load varies greatly and is particularly heavy in the midwestern and southwestern parts of the United States. Natural causes of high phosphate exist in Florida and some parts of Texas. To be meaningful, regulations should be aimed not only at swimmabiltiy and fish, but also at protecting the microorganisms and smaller macroorganisms in streams and lakes that are important in the recycling of waste and the restoring of water quality. Improvements have occurred in the Ohio River where over 100 successful bass tournaments were held in 1975, something that would never have been considered in 1970. Other improvements have been in the Delaware and Connecticut Rivers, and in streams in Maine, where about 67% were found to be fishable and swimmable. Streams in Massachusetts, Connecticut and Pennsylvania also showed improvement as of 1976. The Potomac River in Washington, D.C., is fishable near the city. Out of 642 small streams in Tennessee, 300 to 346 now meet water standards and 258 more will meet them in 1983. The majority of streams in Minnesota, Nebraska, Kansas and Arkansas will also support fish and wildlife in 1983. (Garrison-Omniplan)

River.

The two main water quality problems in Subbasins 14 and 16, the headwater areas of the Upper Allegheny River Basin and the Genesee River Basin, are suspended solids and biodegradable wastes, caused by inadequately treated municipal and industrial waste discharges, and degradation by oil and gas well brines. Tunungwant Creek has high BOD, ammonia, phenol, chlorides and dissolved solids. The planned upgrading of the Bradford treatment facilities will reduce the BOD and ammonia problems. Conewango Creek's main problem is organic suspended material and low dissolved oxygen values which originate upstream in the State of New York. Oil and gas brines are affecting three streams, and sewage discharges at Tionesta are affecting the Allegheny River, but this problem should be alleviated by the proposed Tionesta treatment facilities. Oil Creek has excellent water quality except in the lower two miles, which is severely degraded due to oil pollution and related petro-chemical industrial activities. Incidents of groundwater pollution have occurred as a result of oil production, landfill leachates and industrial waste lagoons. The sediment yield for Subbasins 14 and 16 is 460,000 tons per year. It is recommended that conservation measures be implemented to reduce this problem. Within the subbasin, 22 streams have been designated as candidates for the State Scenic Rivers System. Water supplies within Subbasin 16 are generally abundant, and usage is moderate--175 mgd in 1970. In Subbasin 14, there are only two water suppliers, and both have inadequate supplies to meet existing demands during a drought. (Garrison-Omniplan)

SUBBASIN 11, UPPER JUNIATA RIVER,
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-12, January 1980. 123 p, 18 Fig, 40 Tab, 6 Append.

Descriptors: *Groundwater pollution, *Thermal pollution, *Leachates, *Municipal wastes, *Industrial wastes, *Flood frequency, *Coal mine wastes, *Acid mine drainage, *Wild rivers, Oil pollution, Sediment yield, Soil erosion, Stream pollution, *Pennsylvania, Upper Juniata River.

Subbasin 11 in Pennsylvania typifies the Southern Alleghenies, a rural and sparsely populated area. Most of the population lives in the river valleys, which are prone to damage by flooding. Municipal and industrial development has led to localized water quality problems. Ten reaches of stream are candidates for the Pennsylvania Scenic Rivers System. Water quality problems stem from municipal or industrial waste discharges, malfunctioning on-lot sewage disposal systems, landfill leachate or acid mine drainage. Coal mining occurs to the west and south of Altoona and in Watershed D, which causes acid mine drainage into four streams. The power plant located on the Frankstown Branch Juanita River at Williamsburg causes thermal pollution. However, the plant will be retired soon. On-lot sewage system malfunctions due to inadequate soils are a problem throughout the basin. Groundwater pollution is occuring from septic tanks, landfills, oil tank leaks, seepage from industrial soils. The current sediment yield is 174,000 tons per year; this could be reduced through better conservation practices. With the exception of the Williamsburg Power plant, the largest water supply usage in the basin is for public water supply. Currently 8 of the 42 suppliers would have a source yield deficiency if a drought were to occur. Seven of the companies can meet future yield deficiencies by installing meters, which should reduce the demand. Consumptive water use could be an emerging problem, if crop irrigation during dry years increases. (Garrison-Omniplan)
W84-00839

SUBBASIN 15, LAKE ERIE,
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-15, December 1979. 78 p, 17 Fig, 35 Tab, 6 Append.

Descriptors: *Eutrophic lakes, *Lake soils, *Impaired water quality, *Coliforms, *Urban runoff, *Water pollution sources, *Industrial wastes, *Municipal wastes, *Anaerobic conditions, Water pollution effects, Water pollution control, Dissolved oxygen, Water quality standards, *Pennsylvania, Lake Erie.

The Lake Erie subbasin is one of two areas in Pennsylvania which drains into the Great Lakes and St. Lawrence River. Lake Erie is not only a major factor in the development of the area, but is also a major influence on the climate, making possible better agricultural production than normal for its latitude. Water supply is not a serious problem in Subbasin 15 because the lake provides essentially unlimited amounts of water. A proposed steel plant to be located beside Lake Erie on the Pennsylvania-Ohio State line will strengthen the economy of this region, which includes the manufacturing of electrical and paper products, vineyards, orchards and dairy farms. Lake Erie has had an accelerated eutrophication rate. Pollution from cities as far away as Detroit accumulate in the lake causing decreases in dissolved oxygen and enrichment of aquatic plants. Along the south shore, combined sewer overflows and urban runoff are causing high coliform counts. Correcting the sewer overflow situation should solve most of this problem. All but three of the small streams which drain directly into Lake Erie have high coliform bacteria contamination, and ammonia, iron, phosphate and pH problems due to domestic discharges, septic tank effluents, combined sewer overflows, and urban and agricultural runoff. Deep wells are not possible because of salt water problems. Contamination of groundwater is widespread due to on-lot sewage systems which were in place prior to state regulations. The soils are poorly suited for on-lot disposal. The completion of planned and under-construction treatment plants will greatly improve this overall condition. (Garrison-Omniplan)

STATE WATER PLAN: SUBBASIN 10, LOWER WEST BRANCH SUSQUEHANNA RIVER.
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-11, December 1979. 132 p, 20 Fig, 42 Tab, 6 Append.

Descriptors: *River basins. *Stream pollution, *Agricultural runoff, *Septic tanks, *Septic wastewater, *Industrial waste, *Sediment yield, Fish populations, Groundwater pollution, Leachates, Erosion control, Electric power demand, Long-term planning, Recreation demand, *Pennsylvania, Lower West Branch Susquehanna River.

A series of 23 reports being published as a result of initial ivestigations and studies conducted in connection with the State Water Plan of Pennsylvania includes this area designated as Subbasin 10. Its northern half is in the Appalachian Plateau, and the southern half is in the mountainous Valley and Ridge Province. The overall basin is 66% forested with 22% in agriculture. Most of the water quality problems identified are associated with malfunctioning septic tanks and agricultural runoff. Future mining activities must be carefully controlled to prevent possible degradation. Industrial waste slugs from the Federal Penitentiary near Lewisburg have caused fish kills in Buffalo Creek. Groundwater pollution incidents have occurred as a result of landfill leachates or septic system malfunctions. The average sediment yield of 219,000 tons per year could be reduced through the use of better erosion control measures on privately owned lands. The largest single water user within the basin is the Montour electric power generating plant, which consumes approximately 12.6 mgd. Crop irrigation and public water supplies require significant amounts of water in the basin. There are 21 public water suppliers in the basin. Most of the streams are of good quality and provide good fishing, particularly Loyalsock, Lycoming and Muncy Creeks. (Garrison-Omniplan)
W84-00843

STATE WATER PLAN: SUBBASIN 9, CENTRAL WEST BRANCH SUSQUEHANNA RIVER.

Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-10, February 1980. 132 p, 20 Fig, 43 Tab, 6 Append.

Descriptors: *River basins, *Wilderness areas, *Wild rivers, *Water quality, *Stream pollution, *Acid mine drainage, *Groundwater pollution, *Flood damage, Flood control, Flood protection, Mountains, Iron, Manganese, Scenery, *Pennsylvania, West Central Branch Susquehanna River.

Subbasin 9 in Pennsylvania is roughly 85% wooded, and is set in very mountainous terrain with deep cut streams where the wilderness areas have been largely preserved. Large portions of the area are in state ownership. Subbasin 9 is described in one of 23 reports being published as a result of initial investigations and studies conducted in connection with the State Water Plan of the Commonwealth. The primary water quality problems arise from acid mine drainage and inadequately treated wastewater. Iron and manganese concentrations continue to be excessive downstream of Lock Haven and acid slugs, which reduce the pH to as low as 4.4, have occasionally occurred. There have been some instances of groundwater pollution, particularly in the limestone valleys in the lower portion of the basin. Each year, despite the small population of the area, the subbasin sustains an average of $3.7 million in damages from floods as a result of the large number of communities in the valleys. There are 35 public water suppliers of which eight do not have sufficient source capacity to meet their present needs in a drought. Also covered in the report are goals and objectives, and physical and socio-economic features. (Garrison-Omniplan)

STATE WATER PLAN: SUBBASIN 7, LOWER SUSQUEHANNA RIVER.
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-8, February 1980. 267 p, 20 Fig, 44 Tab, 6 Append.

Descriptors: *River basins, *Flood control, *Water allocation, *Flood protection, *Municipal wastes, *Electric power demand, *Flood plain management, Recreation demand, Streams, Rivers, Groundwater pollution, Nonstructural alternatives, Project planning, *Pennsylvania, Lower Susquehanna River.

Subbasin 7 is a major agricultural area within Pennsylvania and has outstanding soils associated with the limestone valleys. This subbasin is described in one of 23 reports being published as a result of initial investigations and studies conducted in connection with the State Water Plan of the Commonwealth. Streams are used in this subbasin for water supply, waste water disposal, and for industrial and agricultural usages. Urban development has created many water resources problems. Flooding, which was a relatively minor problem in the past, has now become fairly frequent. It was found that very few additional projects could be economically justified, such as a flood control reservoir on Chickies Creek above Manheim or various local protection alternatives in Harrisburg. Fertilizers being used for agriculture and municipal waste discharges are causing algae to grow in many of the streams. Electric power needs are placing a heavy requirement on the Susquehanna River to cool the condensors of the electric generators. Many streams in the basin have outstanding aesthetic qualities and are suitable for fishing and boating. The quality of groundwater in Subbasin 7 is generally good to excellent except for certain limestone regions where nitrate and overall hardness problems exist. Groundwater incidents have occurred, especially from hydrocarbon pollution, which is a serious problem in the Mechanicsburg area. Other problems have been caused by landfill leachates, malfunctioning septic systems, fertilizers, and animal wastes. (Garrison-Omniplan)

STATE WATER PLAN: SUBBASIN 5, UPPER CENTRAL SUSQUEHANNA RIVER.
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-6, December 1978. 168 p, 20 Fig, 40 Tab, 6 Append.

Descriptors: *Rivers, *Stream pollution, *Flood control, *State jurisdiction, *Acid mine drainage, *Coal mines, *Flood protection, Mountains, Municipal wastes, Project planning, Dam construction, Dams, Water quality standards, *Pennsylvania, Upper Central Susquehanna River.

All of Subbasin 5 is within the Appalachian Mountain Section of the Valley and Ridge Province. It includes the drainages of the Lackawanna River and the Susquehanna River from the mouth of the Lackawanna to the confluence with the West Branch Susquehanna. This report is one of 23 being published as a result of the initial investigations and studies conducted in connection with the State Water Plan of the Commonwealth of Pennsylvania. The report outlines goals and objectives, and physical features and climate of the subbasin. In addition, there are recommendations regarding flood damage reduction, water quality and supply, and outdoor recreation. Past coal mining activities have left many of the streams severely polluted with acid mine drainage. In addition, municipal wastes of degrading the streams. The most serious problem in the basin is the flooding caused by runoff from the steep mountainous terrain. With the protection provided by flood control projects now completed or under construction, the residual damages have been reduced to $5.2 million per year. Feasible and recommended dam projects include the proposed Soil Conservation Service dam, PA 665, on Nescopeck Creek in Watershed D; dam site 37-9; and channel modification projects for the communities of Moscow and Conyngham. Planned or completed acid mine drainage abatement projects are expected to improve 23 miles of the Lackawanna River. The most pressing water supply problem is within the Pennsylvania Gas and Water Company system, which services about 428,000 people. (Garrison-Omniplan)
W84-00848

STATE WATER PLAN: SUBBASIN 4, UPPER SUSQUEHANNA RIVER.
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-5, June 1979. 146 p, 19 Fig, 41 Tab, 6 Append.

Descriptors: *River basins, *Stream pollution, *Acid mine drainage, *Industrial wastewater, *Dam construction, Project planning, Long-term planning, State jurisdiction, Flood control, Flood protection, Water pollution control, Scenery, Streams, Rivers, *Pennsylvania, Upper Susquehanna River.

Subbasin 4, which approximates the area known as the Northern Tier Region of Pennsylvania is described in one of 23 reports being published as a result of the initial investigations and studies conducted in connection with the State Water Plan of the Commonwealth of Pennsylvania. Farming had been the primary economic base of the area for many years, but it has been replaced by manufacturing. Fishing and hunting in the area is quite good. Most of the streams are of good quality, however, they tend to flood during storms and usually have low flows during droughts. It is recommended that the construction of both the Tioga-Hammond and Cowanesque Lake projects be completed as soon as possible. The potential Towanda Reservoir site should be studied further to evaluate its flood control, recreation, water supply, low flow augmentation and hydropower potential. The average annual damages in the basin would have been $5.8 million if existing projects had not been built. Eight streams in the basin have been identified as candidates for the Pennsylvania Scenic Rivers System. The Susquehanna River g
has good water quality, but gives evid
excess iron concentrations from acid mine d
upstream, as well as domestic and in
wastewater and sedimentation problems.
pollution, sedimentation and acid mine d
are the main problems on the Tioga River
use in the basin is relatively small, at 423 mg
projections of 66 mgd by 1990. (Garriso
plan)

This is one of 23 reports being published as
of the initial investigations and studies co
in connection with the State Water Plan
Commonwealth of Pennsylvania. Subbasi
cludes all of the direct drainage into the D
River in northeast Pennsylvania above the
River. The fact that this area remains re
undeveloped has made it an ideal area fo
ational development; however, the area i
prone. All of the damage centers in Sub
have had their floodplains mapped and all
are eligible for Federal flood insurance.
Subbasin 1, 16 stream reaches have been s
as candidates for inclusion in the State
Rivers System. The total water use within
sin 1 is currently 547 mgd, of which 511
used by the Portland and Martins Creek
generating plants. There are 35 public wat
pliers in Subbasin 1. Five of these supplie
serve water in Subbasin 2, which results in
being diverted out of the subbasin. Sedime
and erosion problems in this basin are re
small. The quality of surface and groundw
the subbasin is good to excellent, but there
areas where there are significant sources o
tion. Groundwater pollution incidents ha
curred primarily as a result of landfill l
seepage and malfunctioning on-lot dispos
tems. The report lists goals and objectives
resources problems and solution alternati
well as physical features and climate of the
sin. (Garrison-Omniplan)

BOR MANAGEMENT STRATEGIES FOR ENGLAND,
England River Basins Commission, Boston,

Richmond.
rt, September 1981. 48 p, 3 Fig.

riptors: *Harbors, *Management planning, g-range planning, *Interagency cooperation, er policy, *Public policy, *Public access, prehensive planning, Nonstructural alterna-Multiobjective planning, Projections, Coastal management, Area redevelopment, *New and, Northeast U.S.

England harbors possess numerous physical raints to development. The most significant of are a limited land and water base, the high of capital improvements to existing infrastruc-the predominance of private ownership, and resence of many non-water dependent long-uses. In addition, New England's harbor com-ies are limited in their abilities to successfully ve harbor use conflicts because of fragmented r planning, management, and regulations; of a common goal shared by local harbor sts; and lack of legal agreement on the nature public's interest in harbor resources. Unlike Coast states, New England states lack a g legal tradition of fully protecting the pub-interest in harbor resources. New England r communities should establish local harbor gement structures that include both an institu-vith equitable representation from all relevant ictions and public and private interest groups; plan that allocates limited harbor shoreline arbor waters among competing users. Such a ure could range from an informal networking isting agencies and interest groups with a ion set of goals, to a formalized harbor gov-ent with broad planning, management, financ-and regulatory authorities. SPECTS AND STRATEGIES FOR NEW LAND PORTS.
England River Basins Commission, Boston,

rt, September 1981. 68 p, 13 Fig, 7 Tab.

riptors: *Port facilities, *Regional planning, agement planning, *Waterfront facilities, authorities, *Long-range planning, Multiob-e planning, Profit, Property rights, Harbors, omic evaluation, Economic yield, *New Eng-Northeast U.S.

ughout the decade of the 1970s, New England nued to rely heavily on waterborne trade: 80 million tons of cargo annually passed gh the region's 10 major commercial ports. oximately 92% of this waterborne commerce sted of petroleum and petroleum products. direction of trade flows was predominantly nd, as receipts comprised over 90% of total tonnage. Approximately 20% of the total ne of regional waterborne trade has been han-through common-user marine terminals. The nes of cargo shipped through New England's ion-user facilities have remained relatively over the past 15 years and are not projected to grow as rapidly as is trade throughout the South and West. New England's 10 major common-user ports are administered by a variety of port organizations. The region is characterized by one port: the Massachusetts Port Authority, which is substantially more sophisticated in operations than its neighboring ports. Additionally, the New England region is unique in containing four privately-owned common-user facilities. With few exceptions, New England port organizations have minimal marketing and planning capabilities. The majority of New England port facilities have emphasized the capability to handle a variety of neo-bulk (lumber, steel) and bulk (salt, scrap metal) cargoes. While some common-user facilities operate at near capacity, an equal number of facilities operate with excess cargo-handling capacity. (Garrison-Omniplan)
W84-00908

REPORT ON REVIEW OF WATER SUPPLY PLANNING, RECOMMENDATIONS AND STRATEGY FOR WESTERN CONNECTICUT.
Anderson-Nichols and Co., Inc., Newington, CT.
Report prepared for the Western Connecticut Water Supply Council, July 1983. 66 p, 4 Append.

Descriptors: *Water yield, *Safe yield, *Water deficit, *Pipelines, *Potential water supply, *Interagency cooperation, Water supply development, Potential water supply, Yield, Water scarcity, Government interrelations, Water policy, Public policy, Longrange planning, *Connecticut.

The goals of this study were to review the water supply plan for Western Connecticut and to assess available water supply alternatives, institutional issues, small water company issues and data adequacy. A review of safe yields for the existing water supplies in Western Connecticut revealed a continuing inconsistency and inaccuracy of reported safe yields. The utilities project a year 2000 deficit of 5.2 mgd for southern Fairfield County alone, while the Corps of Engineers projects a total deficit of 5.0 mgd for 5 of 13 communities in the entire region for this year. Both the short-term and long-term water supply plans evaluated in the Housatonic River Basin Urban Study on a local and regional basis have legal, financial, institutional, or environmental barriers to implementation. The issues of water policy, legal and legislative needs as well as the issue of Class 'B' waters must be resolved first, in order to properly and thoroughly evaluate water supply plans. Several interconnections are viable alternatives, including a major interconnection between Bridgeport Hydraulic and adjoining communities in southern Fairfield County. This pipeline offers a viable solution to the water supply problems of the area. An analysis was conducted of regional water authorities, and a statewide water supply master plan is suggested. Regarding take-overs of small water companies, greater reliance should be placed on providing financial incentives rather than using state action. (Garrison-Omniplan)

NONPOINT SOURCES,
Johns Hopkins Univ., Baltimore, MD. Dept. of Geography and Environmental Engineering.
M. G. Wolman, and C. E. Chamberlin.
In: Proceedings of the National Water Conference, Water Quality and The Clean Water Act, Philadelphia, Janary 26 and 27, 1982. Academy of Natural Sciences, Philadelphia, July 1982. p 87-100, 16 Ref.

Descriptors: *Nonpoint pollution sources, *Pollution load, *Water pollution sources, *Water pollution effects, *Chemical wastes, *Pesticide toxicity, Water quality, Water quality data, Cost-benefit analysis, Public policy, Water policy, Water quality standards.

Pollutant discharges from both point and nonpoint sources affect the quality of rivers, lakes, estuaries, and ocean shorelines. In 1976 it was reported that after projected reductions of a variety of pollutants such as ultimate BOD, nitrogen, phosphorus, coliforms and several metals, in accord with requirements for BPT and secondary treatment by 1977, substantial loadings would remain for such pollutants as total nitrogen, phosphorus, and fecal coliforms. It was estimated that even after elimination of discharge, 79% of nitrogen, 53% of total phosphorous, 99% of coliforms, but only 11% of oil and grease would remain. The diversity of human activities and natural background across the country results in markedly different sources and characteristics of pollutants, with the result that uniform approaches will not achieve desired objectives. In general, it has been found that the organic content expressed as BOD and COD of runoff and discharges are generally comparable to concentrations found in effluents from secondary sewage treatment plants. Unit yields of sediment from construction sites may exceed previous background values 10 to 50-fold with concentrations on the order of 10,000 mg/1. For planning purposes, models are needed to compare the relative values of expenditures for control of diverse sources of pollutants to achieve given uses. (Garrison-Omniplan)

DETERMINATION OF IRRIGATION PUMPAGE IN PARTS OF KEARNY AND FINNEY COUNTIES, SOUTHWESTERN KANSAS,
Geological Survey, Lawrence, KS. Water Resources Div.
R. J. Lindgren.
USGS Water-Resources Investigations 82-4011, 1982. 26 p, 141 Fig, 2 Tab, 6 Ref.

Descriptors: *Irrigation requirements, *Pumpage, *Soil moisture, Wilting point, Field capacity, Water demand, Evapotranspiration, Consumptive use, Kearny County, Finney County, *Kansas.

Irrigation pumpage was determined for parts of Kearny and Finney Counties in Southwestern Kansas using crop-acreage data and consumptive, irrigation-water requirements. Irrigated acreages for 1974-80 were compiled for wheat, grain sorghum, corn, and alfalfa using records from the U.S. Agricultural Stabilization and Conservation Service. Consumptive-irrigation requirements were computed using a soil-moisture model. The model tabulated monthly soil-moisture and crop-water demand for various crops and computed the volume of irrigation water needed to maintain the available moisture at 50% for loamy soils or at 60% for sandy soils. Irrigated acres in the study area increased from 265,000 acres during 1974 to 321,000 acres during 1980. Irrigation pumpage increased from 584,000 acre-feet during 1974 to 738,000 acre-feet during 1980. Decreased consumptive-irrigation requirements during 1979 resulted in a comparatively small irrigation-pumpage estimate of 458,000 acre-feet. (USGS)

THE STATE WATER PLAN, SUBBASIN 17, CENTRAL ALLEGHENY RIVER.
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-17, December 1980. 146 p, 21 Fig, 48 Tab, 6 Append.

Descriptors: *Groundwater movement, *Groundwater potential, Groundwater availability, *Aquifer characteristics, *Acid mine drainage, *Strip mine wastes, *Surface water, Groundwater level, Aquifers, Mine wastes, Fuel, Industrial wastes, Coal mine wastes, Gasoline, Oil pollution, *Pennsylvania, Allegheny River.

The rugged terrain of the Appalachian Plateaus Province characterizes Subbasin 17 in Pennsylvania, where roughly two-thirds of the land is forested and one-sixth is in agriculture. The area's economy is largely based on its minerals. Coal, gas and

oil have been mined heavily in the past; coal is the major mineral resource being mined today. Abandoned coal mines, both deep and strip, as well as abandoned oil wells and gas wells are responsible for the degradation of many streams by acidity and iron. The scenic streams in the rugged terrain are valuable resources that have been despoiled by pollution. The quality of fishing in most of the streams is generally low. While the surface waters in the basin are largely polluted by acid mine drainage, the groundwaters are generally good. The exception occurs in the Claron County area where previous mining activities and inter-connected abandoned gas wells have caused widespread groundwater pollution. Water quality problems of Subbasin 17 are being examined and water quality standards and wastewater treatment plans are being developed. The heaviest water use in the subbasin occurs in the southern portion, which has two existing electric power stations, and 77 mgd of self-supplied industrial water use. These uses alone account for 312 mgd out of a total of 368 within the basin. Consumptive water use in the subbasin currently is 30 mgd and is projected to increase to 64 in 1990. It is recommended that low head hydropower studies be conducted in this subbasin. There are 56 public water suppliers in the basin, of which 48 have developed their own sources of supply. (Garrison-Omniplan)
W84-00784

THE STATE WATER PLAN, SUBBASIN 19, MONONGAHELA RIVER.
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-19, July 1982. 175 p, 21 Fig, 48 Tab, 6 Append.

Descriptors: *Stream pollution, *Stream improvement, *Rivers, *Coal mine wastes, *Waste pollution control, *Water quality control, *Water pollution sources, Steel industry, Industrial wastes, Acid mine drainage, Sewers, Surface water, *Pennsylvania, Monogahela River.

The abundance of coal and associated mining activities have created a serious water quality problem in the Monongahela River in Pennsylvania. It has also indirectly led to a water supply problem in the basin because of the concentration of steel and related industries, as well as power generation facilities whose daily water use totals over three billion gallons. The overall problems of the subbasin point to the particularly serious need for the construction of the Rowlesburg Reservoir on the Cheat River in West Virginia. Many alternatives have been explored but this is the only project which offers a viable solution to all of the problems which exist on this river. Although mine acids have been significantly reduced, concentrations of total dissolved solids and sulfates during low flow periods occasionally exceed the acceptable standards of 500 mg/l and 250 mg/l in the river by more than 75%. An examination of the tremendous costs involved in treating these pollutants points to the only feasible economic solution: streamflow augmentation. By releasing water for storage during low flows, pollutants would be diluted to acceptable standards. Other water quality problems which have been identified in this area include urban stream drainage, including combined sewer flows; various of nonpoint sources; thermal pollution; landfill leachate; and excessive mineral constituent concentrations in surface and groundwaters. The most critical water supply problem is the conflict between the water supply uses of the river during low flow periods and the use of the river for commercial navigation. (Garrison-Omniplan)

MORRIS COUNTY MASTER PLAN: WATER SUPPLY ELEMENT.
Killman (Elston T.) Associates, Inc., Millburn, NJ.
Report submitted to the Morris County Planning Board, N.J., October 1982. 94 p, 7 Tab, 16 Ref, 4 Append, 4 Plates.

Descriptors: *Long-term planning, *Water supply, *Water demand, *Water supply development, *Alternative planning, Administrative regulations, Water costs, Areal hydrogeology, Groundwater, Water quality, Groundwater pollution, Wells, Chemical analyses, Regional planning, Aquifers, *New Jersey, Morris County.

The recent drought and water supply shortage which affected northern New Jersey has illustrated the need for ample water supply reserves and long range planning. The study examines these issues and presents recommendations which would improve the quality and reliability of water supply services in Morris County. Water supplies are ample and are derived from both surface and groundwater sources, with groundwater accounting for the greatest percentage of water consumed. This report highlights the County's dependence on its subsurface aquifers, locates them, and forms a starting point from which local municipalities can take steps to further protect their drinking water supplies. The study analyzes water supply sources, facilities, consumption patterns, and future needs. Extensive development and diversion of surface water out of the County has reduced available supplies. In recent years, episodes of groundwater contamination have jeopardized or closed several municipal supplies. Responsibility for management and distribution of potable water in Morris County is vested in numerous independent water companies, both public and private. Thus, implementation of long-term water supply management strategies can be difficult. This report defines the role of the Morris County Municipal Utilities Authority in overcoming that problem. SUBBASIN 13, POTOMAC RIVER.
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-14, June 1979. 98 p, 18 Fig, 39 Tab, 6 Append.

Descriptors: *Industrial wastes, *Rivers, *Stream pollution, *Reservoirs, *Interstate rivers, *Water quality standards, *Irrigation requirements, Recreation, Water conservation, Conservation, Legal aspects, State jurisdiction, Wild rivers, *Pennsylvania, Potomac River basin.

Water use in Subbasin 13 in Pennsylvania is relatively light; the greatest increase in usage is expected to be for crop irrigation. Current usgage is 23.1 mgd and is projected to grow to only 49 mgd in 1990. Public water supply is the largest use in the basin, amounting to 7.8 mgd. There are 24 public water suppliers of which all but seven serve fewer than 1,000 customers. Most of the suppliers get their water from wells or springs. It is strongly recommended that applicable conservation measures be applied by all suppliers whose residential gpcd exceeds 50 or whose industrial usage appears excessive. The Potomac River Basin is besieged with interstate water issues because the metropolitan Washington, D.C. area is short of water and badly needs reservoir development upstream. One project, Sixes Bridge Reservoir on the Monocacy River in Maryland, would back water just across the Pennsylvania border into Adams County. Because of the projected irrigation demands in Pennsylvania, there is a potential conflict between Pennsylvania's right to the water flowing into the reservoir and the water supply interests downstream. Flooding in this basin is a minor problem. There are many opportunities for water-related outdoor recreation in Subbasin 13. In the future, additional picnic tables, swimming pools and flatwater for power boating will be needed. Three streams have been selected as candidates for the State's Scenic Rivers System. There are a few local groundwater quality problems from nutrient enrichment by agricultural runoff, improperly treated sewage, malfunctioning on-lot disposal systems and industrial waste discharges. (Garrison-Omniplan)
W84-00841

SUBBASIN 12, LOWER JUNIATA RIVER.
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-13, June 1979. 104 p, 19 Fig, 40 Tab, 6 Append.

Descriptors: *Flood frequency, *Irrigation requirements, *Sediment yield, *Soil erosion, *Surface water, *Rivers, Leachates, Conservation, Industrial wastes, Raw wastewater, Treatment facilities Silt, Water supply, *Pennsylvania, Upper Junita River.

About two-thirds of Subbasin 12 in Pennsylvania is forested, and one-quarter is farmland. This valley has become a center for the Amish sect, a religious group well known for their farming abilities. The urban centers in the basin are located primarily along the Juniata River. Flood damage is common occurrence in this basin because of the mountainous terrain surrounding the communities along the river. There are 20 damage centers and 22 damage reaches identified which have existing flood problems. There are 21 public water suppliers in the basin, of which 20 have their own sources of supply. The total water use in the basin in 1970 was 48 mgd, of which nearly 38 mgd was for self-supplied industry. If agricultural crop irrigation grows as projected, this may be one of the largest water uses in the future. Streamflows will be diminished if surface streams are used as the water source. There have been a few reported incidents of groundwater pollution from seepage of landfill leachates and malfunctioning septic systems. Erosion in the basin is a problem because of the extensive farming of agricultural land, which accounts for the slightly above-average sediment yield of 86 tons/sq. mile from the basin. It is recommended that agricultural conservation plans be implemented to reduce this problem. Inadequately treated industrial wastes, raw domestic wastewater and siltation are problems in Kishacoquillas Creek; however, the planned construction of Brown and Armagh Townships' treatment facilities should alleviate these wastewater problems. Subbasin 12 is ideally suited for many water-related outdoor recreational pursuits. (Garrison-Omniplan)
W84-00842

STATE WATER PLAN: SUBBASIN 6, LOWER CENTRAL SUSQUEHANNA RIVER.
Pennsylvania Dept. of Environmental Resources, Harrisburg. Office of Resources Management.
Report SWP-7, January 1980. 138 p, 20 Fig, 41 Tab, 6 Append.

Descriptors: *River basins, *Flood control, *Flood protection, *Electric power demand, *Dam construction, *Project planning, *Agriculture, *Long-term planning, Coliforms, Water quality standards, Recreation demand, Nonpoint pollution sources, *Pennsylvania, Lower Central Susquehanna River.

The Susquehanna River is a vital artery in the development of Subbasin 6, which lies entirely within the Valley and Ridge portion of Pennsylvania. This subbasin is described in one of 23 reports being published as a result of initial investigations and studies conducted in connection with the State Water Plan of the Commonwealth. The river supplies water for manufacturing and cooling of condensors for electric power generation, in addition to recreation opportunities. Very intense farming, which results in the area being the second leading crop producer in Pennsylvania, will mean increasing demands on the water resources for irrigation and will also increase nonpoint pollution to the streams. This area has also experienced intense flooding. To further reduce problems in the Middle Creek watershed, it is recommended that dams PA-636 and PA-638, floodway PA-639, and dike PA-640, be constructed as soon as possible. In the less populated areas, water quality is generally good except where polluted tributaries feed into it, such as at the mouths of Shamokin and Mahanoy Creeks. Also, there have been some algae blooms and high coliform concentrations in the Sunbury area. The report lists goals and objectives, and physical features and climate of the subbasin. (Garrison-Omniplan)

ER, WATTS, AND WILDS: HYDRO-
VER AND COMPETING USES IN NEW
LAND.
England River Basins Commission, Boston,

l Report of the New England River Basins
mission's Hydropower Expansion Study,
ust 1981. 136 p, 14 Fig, 25 Tab, 5 Append.

riptors: *Dams, *Hydroelectric power, *Elec-
power costs, *Hydroelectric plants, *Electric
er production, *Electrical equipment, Dam ef-
, Environmental effects, Regional planning,
tric power, Electric potential, Economic as-
, *New England, Northeast U.S.

BC has identified 320 existing or breached
sites in New England which could be retro-
l to generate hydroelectricity at an estimated
of 125 mills ($.125) per kilowatt hour or less.
e sites are the most economically attractive
screened from an inventory of over 10,000
throughout the six-state region. The total
rating capacity which could be developed at
320 sites ranges from 300 to 600 megawatts.
BC also identified 44 sites where no dams
ently exist and where power could be generat-
or an estimated cost of 115 mills per kilowatt
or less. The total generating capacity which
l be developed at these 44 sites ranges from
o 475 megawatts. Hydropower currently con-
tes between 4% to 6% of the electricity gen-
d annually in the region. If all of the 320
ing and breached dams that ranked most fa-
bly in the NERBC analysis were retrofitted
power plants, they could generate about 2
on megawatt hours, providing an additional
avings of 3.5 million barrels, or about 4.5% of
ent consumption. Some competing uses are
y to cause conflict, although not every impact
ydro development is necessarily negative.
ever, opposition to the construction of new
at previously undeveloped sites is likely to be
antial. (Garrison-Omniplan)

er supply forecasting typically is based upon
umented records from the recent past ranging
recent year-of-record data to 30-year 'nor-
', and, rarely (because of the lack of records),
year extremes. This report examines 144 years
nstrumented records at Amherst, Massachu-
, 400 years of proxy records from tree rings,
es, newspapers, and other historical records,
the records of thousands of years of archeaolo-
l data in order to evaluate the extent to which
ric and prehistoric climatic cycles might pro-
models for the future. The authors suggest
although long-term past data are poorly docu-
ted, historians should make more use of data
ch can be reasonably verified. The authors
d no clear statistical patterns or cyclicity in climatological records for the Amherst area. Neither do instrumented data support Nineteenth Century newspaper and diary accounts or archaeological reports. Nevertheless, climatologists, archaeologists, and historians seem to overrate climatological factors while, at the same time, downgrading historical data beyond the recent past and failing to employ tests of statistical significance. The humid Northeast would seem to have broader stress tolerances than assumed by some environmental activists, but greater limits than assumed by many developers and planning activists.

OCCURRENCE AND USE OF GROUND WATER IN THE VENICE-ENGLEWOOD AREA, SARASOTA AND CHARLOTTE COUNTIES, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
H. Sutcliffe, Jr., and T. H. Thompson.
USGS Open-File Report 82-700, 1983. 59 p, 21 Fig, 8 Tab, 14 Ref.

Descriptors: *Groundwater availability, *Groundwater quality, Aquifers, Water use, *Florida, Floridan aquifer.

In a 75-square-mile area of coastal Sarasota and Charlotte Counties, demand for water is increasing. Groundwater, the principal source of supply, is distributed largely by public water systems. Principal water-bearing formations in descending order, include the surficial aquifer, artesian zone 1 in the Tamiami Formation, zone 2 in the upper part of the Hawthorn Formation, zone 3 in the lower part of the Hawthorn Formation and upper part of the Tampa Limestone, and zones 4 and 5 which comprise the Floridan aquifer. The surficial aquifer, except near tidewater, provides limited supplies of freshwater to wells. Artesian zone 1 is the major aquifer for public supply. It is contaminated by saline water in some areas, either as a result of inundation by storm-driven tides or by upwar leakage of mineralized water from underlying aquifers through uncased or improperly constructed wells. The city of Venice obtains some water from zone 2, but the water is brackish in much of the area. The water is suitable for irrigation in parts of the area. Except for local use of water for watering livestock and maintaining ponds, the water from zones 3, 4, and 5 is little used because of its poor quality. (USGS)

PUMPAGE OF WATER IN LOUISIANA, 1980,
Geological Survey, Baton Rouge, LA. Water Resources Div.
W. H. Walter.
Louisiana Department of Transportation and Development, Baton Rouge, Water Resources Special Report No 3, 1982. 15 p, 3 Fig, 3 Tab, 25 Ref.

Descriptors: *Water utilization, *Louisiana, Withdrawal, Groundwater, Surface waters, Saline water, Consumptive use, Aquifers, Water supply, *Water use, *Pumpage, *Water-use trends, Domestic use, Public-supply use, Rural use, Irrigation use, Industrial use, Thermoelectric use, Livestock use, Per-capita use.

In 1980 an estimated 12,500 million gallons per day of water was pumped for various uses in Louisiana; 10,700 million gallons per day was pumped from surface-water sources and 1,780 from ground water. Two-thirds of the surface-water withdrawals were from the Mississippi River, mainly for industrial use; and about 56% of the ground water was pumped from the Chicot aquifer in southwestern Louisiana, mainly for irrigation. Total withdrawal use of water in the State increase by 6%, 1975-80. Use of surface water increased by 5% while use of ground water increased by 14%. (USGS)

INTERSTATE WATER LAW ISSUES: UNILATERAL STATE LEGISLATION, ORIGINAL SUITS IN THE SUPREME COURT, INTERSTATE COMPACTS,
North Carolina Univ. at Chapel Hill. Inst. of Government.
M. S. Heath, Jr.
Available from the National Technical Information Service, Springfield, VA 22161 as PB84-140532, Price codes: A04 in paper copy, A01 in microfiche. North Carolina Water Resources Research Institute Completion Report, September, 1983. 48 p, 85 End notes. OWRT A-121-NC(b)(2), 14-34-0001-2135.

Descriptors: *Water law, *Interstate compacts, *Legal aspects, Legislation, *Judicial decisions, Water importing, State jurisdiction, Proprietary power, Constitutional law, Groundwater, Surface water, Equitable apportionment, Riparian rights.

The principal legal avenues for resolving interstate water disputes involve either legislation, litigation or interstate cooperation. This report addresses one option in each of these categories that may be available to state governments: unilateral state legislation designed to restrict outsiders from access to a state's water resources; original actions against a neighboring state in the U.S. Supreme Court; and interstate compacts. The opportunities for unilateral state legislation have been severely restricted by recent Supreme Court decisions, though several developing areas of constitutional law should be monitored closely for their possible future impact on this subject. Original actions in the Supreme Court may offer the possibility that the court will place some limitations on withdrawal of interstate waters by a state, and this possibility may provide some leverage for another state that wants to contest this withdrawal, but original actions are beset by a number of obstacles and uncertainties. The interstate compact has long been regarded as a preferred enforceable alternative for resolving a water resources dispute - if you can get it.

Available from the National Technical Information Service, Springfield, VA 22161 as PB84-140540, Price codes: A03 in paper copy, A01 in microfiche. North Carolina Water Resources Research Institute Completion Report, September, 1983. 48 p, 49 End notes. OWRT A-121-NC(a)(1), 14-34-0001-2135.

Descriptors: *Institutional constraints, *Legal aspects, *Political aspects, *Water supply, Water quality, *Interstate commissions, Water supply development, *Water quality management, Political constraints, Policy making, Legislation, Water laws, Administrative decisions, State jurisdiction, Water allocation, Interbasin transfers, Riparian rights, Interstate compacts, Eutrophication, Surface water, Groundwater.

The purpose of this report was to outline the problems, alternative solutions, and institutional arrangements associated with interstate issues of

managing water supply and water quality between North Carolina and Virginia. In this process, a political analysis was conducted, which indicated that because of inequalities in the distribution of costs and benefits associated with water resource use between parties on different sides of the state line, officials of the respective states do not share a common set of interests or political agenda. This conflict of interest could lead to either a benign neglect of water resource problems of the area, court actions, or the development of an institutional framework for the settlement of differences between interested parties and the management of water resources on an interstate, regional basis. The greatest impediment to the evolution of an interstate institution is the lack of state legislation upon which such an entity could be based. Given the legal status quo, the only positive steps that can be taken in the short run in the absence of legislation are executive and administrative actions, which over the long run, may be unstable and subject to change.

Descriptors: *Water rights, *Storage right, *Reservoir right, *Reservoir storage right, *Drought, *Federal nonreserved rights, Appropriation, Storage, Reservation right, Safe yield, Low-flow frequency curve, Condemnation, Federal reserved rights, Water quality.

Water is stored to protect against natural fluctuations. Kansas statutes are unclear relative to existence of such rights other than that obtainable by the Kansas Water Office. But the Division of Water Resources (DWR) has long recognized storage rights. Detailed procedures exist for obtaining the water reservation right from the Chief Engineer of the DWR by the Kansas Water Office. Federal law requires state assurance for payment for space used for municipal and industrial water storage. The reservation right has some similarities with an appropriation right, including a listing of priority dates and specification of quantity limitation. Once obtained, the reservation right is subject only to federal government condemnation. Concern has risen about protecting water quality releases made by the Corps of Engineers. This concern remains unsolved. Several possible solutions, including one in the Water Plan Storage Act, do exist, however. The Federal Government has a water right for storage designated for various authorized purpose. But the law is unclear, particularly in Corps of Engineers reservoirs, as to the exact nature of such right. It could arguably be a federal reserved right or another species of rights denominated as a federal non reserved right.

APPRAISAL OF THE INTERCONNECTION BETWEEN THE ST. JOHNS RIVER AND THE SURFICIAL AQUIFER, EAST CENTRAL DUVAL COUNTY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
R. M. Spechler, and R. B. Stone, Jr.
USGS Water-Resources Investigations Report 82-4109, 1983. 34 p, 14 Fig, 3 Tab, 33 Ref.

Descriptors: *Surface-groundwater relationship, *Saline water intrusion, Hydrogeology, Aquifers, Water quality, Channel improvements, St. John River, *Surficial aquifer, Limestone unit, *Florida, Duval County.

The proposed deepening of the navigation channel in the St. Johns River to about 46-48 feet below sea level (45 feet below mean low water) may breach up to 11 feet of limestone unit of the lower part of the surficial aquifer along a 25-mile channel. The limestone supplies water to numerous domestic wells along the river in the Jacksonville area. Recent channel improvements to about 39 feet below sea level have already breached the limestone at many locations. Where breaching has not yet occurred, less than 1 to 6 feet of undifferentiated sediments overlie the limestone. These sediments, consisting predominantly of sand, are generally too permeable to form an effective confining layer. Chloride concentrations determined from water in wells tapping the limestone unit range from 8 to 6,600 milligrams per liter. However, chloride concentrations in water from wells located more than 500 feet from the river, were generally less than 30 milligrams per liter. The proposed dredging operation is not expected to alter significantly the present hydrologic system. The current position of the interface most likely represents conditions that will be present after future channel improvements. (USGS)

EVALUATION OF THE STREAM-FLOW DATA IN PENNSYLVANIA,
Geological Survey, Harrisburg, PA. Water Resources Div.
H. N. Flippo, Jr.
Available from the National Technical Information Service, Springfield, VA 22161 as PB83-202002, Price codes: A04 in paper copy, A01 in microfiche. USGS Water Resources Investigations 82-21, December 1982. 56 p, 7 Fig, 8 Tab, 14 Ref.

Descriptors: *Network analysis, *Data collection, *Pennsylvania, Network design, Regional analysis, Gaging stations, Hydrologic data.

The potential for improvement of currently adopted data-transfer mechanisms, which consist of a series of regression equations that relate low-, mean-, and flood-flow characterististics, is evaluated by the technique known as Network Analysis for Regional Information (NARI). This evaluation showed that little improvement in the data-transfer mechanisms can be expected as a result of continued operation of various combinations of gages for as long as 25 years. Therefore, it is proposed that all current gages that are neither managerial nor design specific in purpose (are proposed to be) be discontinued when records adequate for definition of flow characteristics at the gaging site have been collected. Types of data collected, their most commonly used summarizations, and known usage of site-specific data are tabulated. This report cites 14 references. (USGS)

FLOOD OF JUNE 13-15, 1981, IN THE BLANCHARD RIVER BASIN, NORTHWESTERN OHIO,
Geological Survey, Columbus, OH. Water Resources Div.
E. E. Webber.
USGS Water-Resources Investigations 82-4044, 1982. 32 p, 16 Fig, 5 Tab, 4 Ref.

Descriptors: *Flood data, *Flood profiles, Floods, Flood recurrence interval, Rainstorms, Blanchard River Basin, *Ohio.

The flood of June 13-15, 1981, in the Blachard River Basin in Northwestern Ohio caused major damage in Findlay, Ottawa, and adjacent rural areas. Approximately 25% of Findlay and 55% of Ottawa were flooded. Estimated crop damage was $12 million in Hancock County, $7 million in Wyandot County, and $3 million in Putnam County. During the 1981 flood, the maximum gage height of the Blanchard River at Findlay was 17.43 feet, gage datum. This was 0.67 foot higher than the previous peak of record of 16.76 feet that occurred February 11, 1959. The corresponding peak discharge, 13,000 cubic feet per second, was estimated to have a recurrence interval of 50 years. Recurrence intervals of peak flows at other locations on the Blanchard River and on tributary streams were estimated to range from 25 to more than 100 years. Records of precipitation, peak and daily stream discharges, and minimum stream level profiles are given. (USGS)

WATER RESOURCES RESUME: STATE ATLAS SHEET NO. 23, PARTS OF BERGEN, MORRIS AND PASSAIC COUNTIES,
New Jersey Bureau of Geology and Topography, Trenton.
K. Widmer, H. Kasabach, and P. Nordstrom.
New Jersey Geological Survey, Geologic Report Series No 10, 1966. 34 p, 4 Fig, 2 Append.

Descriptors: *Geologic formations, *Water supply, *Wells, *Groundwater availability, Physiographic provinces, Catchment areas, Watersheds, Topography, Surface water, Drilling, *Atlas, *New Jersey, Bergen County, Morris County, Passaic County.

The text, when used with an accompanying overlay and State Topographic Atlas Sheet, will provide a convenient source of information as to the availability of groundwater, major surface water supplies, topography, and other essential factors which affect the water resources in the various counties and municipalities of the northeastern part of New Jersey. The report has been compiled from records available in the Bureau of Geology. It includes a list of 280 wells. Public water supply wells giving more than 100,000 gallons per day, as well as all private wells of similar capacity whose records are on file with the Department of Conservation and Economic Development, have been plotted on the overlay. Within the Atlas Sheet 23 area, there are over 275 wells. The majority of these wells, at the time they were drilled, had a capability in excess of 300,000 gallons per day. Five geologic formations in the study area must be considered when drilling a well. Four are shown on the overlay map, while the fifth, the Pleistocene deposits, must be considered separately as a potential source of water in restricted areas. Successful wells in any of the geologic formations are completed within 400 feet of the surface. Nearly all of the area east of Saddle River is within the franchise area of the Hackensack Water Company. The surface water resources of the Hackensack Basin are completely developed. (Fazio-Omniplan)

STATISTICAL SUMMARIES OF NEW JERSEY STREAMFLOW RECORDS,
S. L. Laskowski.
Water Resources Circular 23, New Jersey Dept. of Environmental Protection, Trenton, 1970. 264 p, 3 Fig, 21 Ref, 1 Append.

Descriptors: *Daily hydrographs, *Data acquisition, *Hydrologic data collections, *Statistical analysis, *Stream discharge, *Stream gages, *On-site data collection, Gages, Flow, Statistical methods, Statistics, Parametric hydrology, Data collections, *New Jersey.

The records for 79 of approximately 100 stream-gaging stations presently or previously operated in New Jersey, plus records for three stations in Pennsylvania, and one in New York are presented in summarized form. In addition to including a greater number of stations in this report, more years of record and more tables are listed for each station than in the 1958 report. A description of the station, three arrangements of data summarizing the daily flow records, and one table listing statistics of the monthly mean flows are provided. No data representing instantaneous extreme flows are given. Plotting positions for the three types of curves describing the characteristics of daily discharge are listed for each station. Statistical parameters are also presented so that alternate curves may be drawn. All stations included in this report have five or more years of record. The data presented are based on observed flow past the gaging station. Since any streamflow record is a sample in time, the data derived from these records can provide only a guide to expected future flows. For this reason the flow records are analyzed by statistical techniques, and the magnitude of sampling errors should be recognized. These analyzed data will be useful to a large number of municipal, state, and federal agencies; industries; utilities; engineers; and hydrologists concerned with the availability, conservation, control, and use of surface waters. The tabulated data and curves can be used to select sites for water supplies and to determine flood or drought storage requirements. The statistical values presented herein can be used in computer programs. (Garrison-Omniplan)

SEMIANNUAL WATER-LEVEL AND POTENTIOMETRIC CONTOURS OF TWO WATER-YIELDING ZONES IN THE SURFICIAL AQUIFER, 1975-79, NAPLES, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
R. C. Buchmiller.
USGS Open-File Report 82-120, 1982. 2 Maps, 25 Fig, 2 Tab, 6 Ref.

Descriptors: *Aquifers, *Potentiometric levels, *Water level fluctuations, Water supply, Water table, *Maps, *Florida, Collier County, Naples.

Potable ground water in the Naples area along the coastal ridge of western Collier County, Florida, is available from two principal sources--the water-table zone and the pumped zone, both within the surficial aquifer. The primary source of public supply is from the pumped zone, locally known as the Coastal Ridge aquifer. Water levels in wells in the pumped zone respond rapidly to pumpage and usually indicate a cone of depression in most of the highly urbanized Naples area. The cone of depression caused by pumpage has created significant water-level differences between the water-table zone and pumped zone. Water-level differences in the two zones from 1975 to 1979 frequently exceed 10 feet. The maps have been drawn to be representative of hydrologic conditions in both zones for the wet and dry seasons from 1975-79. (USGS)
W84-00803

SATURATED THICKNESS OF THE HIGH PLAINS REGIONAL AQUIFER IN 1980, NORTHWESTERN OKLAHOMA,
Geological Survey, Oklahoma City, OK. Water Resources Div.
J. S. Havens.
USGS Water Resources Investigations Open-File Report 82-760, September 1982. 2 Sheets, 7 Ref.

Descriptors: *Groundwater, *Aquifers, Saturation, Bedrock, *Oklahoma, *High Plains Regional Aquifer System, *Maps.

The High Plains aquifer in Oklahoma is part of regional aquifer system extending from South Dakota southward to Texas and New Mexico. The principal aquifer, the Ogallala Formation of Tertiary age, is hydraulically connected with other unconsolidated deposits, principally of Quaternary age. During 1978, the U.S. Geological Survey began a 5-year study of the High Plains regional aquifer system to provide hydrologic information for evaluation of the aquifer and to develop and evaluate predictive computer models of it. This report consists of two maps showing the 1980 saturated thickness of the High Plains regional aquifer in northwestern Oklahoma. The saturated thickness was derived from published reports showing the aquifer base and the 1980 water table; the difference in altitude between these two surfaces gives the saturated thickness of the aquifer. CHEMICAL QUALITY OF WATER IN THE UPPER PART OF THE FLORIDIAN AQUIFER, DUVAL COUNTY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
H. Thompson.
USGS Water Resources Investigation Open-File Report 82-119, 1982. 1 Map, 5 Fig, 1 Tab, 10 Ref.

Descriptors: *Groundwater, *Water quality, *Florida, Chlorides, Dissolved solids, Hardness(Water), Atlantic Coastal Plain, Floridian Aquifer, Chemical water types, Duval County, Water chemistry, *Maps.

Between 1977 and 1980, water samples from 211 wells that penetrate as much as 900 feet of the upper part of the Floridian aquifer were analyzed for major inorganic ions. Maps show the areal distribution of dissolved solids, total and noncarbonate hardness, chloride, and chemical water types. Variation in water quality with aquifer depth was not considered. In general, the concentrations of the constituents were lowest in the southwest area of the county, and highest in the southeast. Ranges of concentrations (in milligrams per liter) were: dissolved solids, less than 200 to as much as 623; total hardness as calcium carbonate, less than 200 to as much as 430; and chloride, less than 10 to as much as 210. Noncarbonate hardness ranged from less than 30 to as much as 70% of the total hardness. Six chemical types were defined, based upon the predominant cations and anions. The most prominent type was a calcium sulfate mass extending into central Duval County from the southeast. Calcium bicarbonate and calcium-magnesium bicarbonate types were found in most of the rest of the county. (USGS)

Geological Survey, Tallahassee, FL. Water Resources Div.
A. D. Duerr, and J. T. Trommer.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224197, Price codes: A04 in paper copy, A01 in microfiche. USGS Water Resources Investigations 82-17, 1982. 49 p, 14 Fig, 4 Tab, 10 Ref.

Descriptors: *Irrigation water, *Water use, Crops, Irrigation systems, Southwest Florida Water Management District, *Florida.

Irrigation water-use data are summarized in this report for 74 farms in the Southwest Florida Water Management District. Most data are for 1978-90, but 18 farms have data extending back to the early 1970's. Data include site number and location, season and year, crop type, irrigation system, monitoring method, and inches of water applied per acre. Crop types include citrus, cucumbers, pasture, peanuts, sod, strawberries, and tropical fish farms are also included. Water-application rates per growing season ranged from 0 inches per acre for several citrus and pasture sites to 239.7 inches per acre for a nursery site. The report also includes rainfall data for 12 stations throughout the study area. (USGS)

Descriptors: *Potentiometric level, Groundwater, Hydrologic aspects, Aquifer, Hydrogeology, *Florida, St. Johns River Water Management District, *Maps.

This map presents the potentiometric surface of the Floridan aquifer in the St. Johns River Water Management District and vicinity for May 1982. The Floridan aquifer is the principal source of potable water in the area. Water-level measurements were made on approximately 1,000 wells and on several springs. The potentiometric surface is shown mostly by 5-foot contour intervals. In the Fernandina Beach area 20-foot intervals are used to show a deep cone of depression. The potentiometric surface ranged from 128 feet above NGVD (National Geodetic Vertical Datum of 1929) in Polk County to 68 feet below NGVD in Nassau County. Because of above average rainfall, water levels began to recover from record low levels set in September 1981 in many counties. Except in a few places, water levels throughout the District rose above May 1981 levels. May 1982 levels were as much as 9 feet and commonly 1 to 3 feet higher than the below normal May 1981 levels. ANNUAL SUMMARY OF GROUND... CONDITIONS IN ARIZONA, SPRING ... SPRING 1982,
Geological Survey, Tucson, AZ. Water R... Div.
USGS Open-File Report 82-1009, Februa... 2 Sheets, 5 Fig, 2 Tab, 19 Ref.

Descriptors: Water levels, *Water-leve... ations, *Pumpage, Irrigation, *Arizona, E...

ıge lowlands province, Central highlands prov-
e, Plateau uplands province, *Withdrawal,
aps, *Groundwater.

e withdrawal of ground water was about 5.4
ion acre-feet in Arizona in 1981, which is about
,000 acre-feet more than the amount withdrawn
980. Most of the increase in 1981 was in the
unt of ground water used for irrigation in the
in and Range lowlands province. Through
l, slightly more than 189 million acre-feet of
nd water had been withdrawn from the
nd-water reservoirs in Arizona. The report
ains two small-scale maps that show ground-
er pumpage by areas and the status of the
nd-water inventory in the State. The main
, which is at a scale of 1:500,000, shows poten-
well production, depth to water in selected
s in spring 1982, and change in water level in
ted wells from 1977 to 1982. A brief text
marizes the current ground-water conditions in
State. (USGS)

analysis, *Networks, *Kriging, Universal
, *Variogram, Semi-variogram, Geostatis-
nterpolation, Stochastic interpolation, Block
, Drift estimation, Autocorrelation, Infor-
value.

m K603 contains procedures necessary for
ochastic-interpolation algorithm known as
sal kriging, as originally described by G.
ron. By specifying a theoretical semi-vario-
nd functional terms of an assumed underly-
nd, or drift, kriging provides unbiased esti-
mates of values of variables in neighborhoods of autocorrelation. Given single observations and their spatial or temporal distribution the technique yields point estimate variances at arbitrary locations. In the absence of measurement errors, which can be incorporated in the analysis, kriging is an exact interpolator. The program includes four procedures used in kriging: (1) semi-variogram estimation; (2) universal kriging for optimization of the drift-variogram set; (3) universal kriging for arbitrary point or block estimation; and (4) universal kriging for drift-coefficient estimation. In addition, an option to apply kriging in block-estimation problems is also included. (USGS)

FLOODS OF NOVEMBER 1978 TO MARCH 1979 IN ARIZONA AND WEST-CENTRAL NEW MEXICO,
Geological Survey, Tucson, AZ. Water Resources Div.
B. N. Aldridge, and T. A. Hales.
USGS Open-File Report 83-201, April 1983. 168 p, 13 Fig, 10 Tab, 38 Ref.

Descriptors: *Floods, *Flood damage, Hydrographs, *Peak discharges, *Regulated flow, *Reservoir storage, Discharge(Water), Historic floods, Precipitation(Atmospheric), Reservoir operation, Stream erosion, Streamflow, Surface runoff, Traveltime(Floods), *Gila River, Little Colorado River Maricopa County, Phoenix, Salt River, Santa Cruz River, San Pedro River, Verde River, San Francisco River, Duncan, Clifton, Safford, Winslow, Gila Hot Springs, *Arizona, *New Mexico.

Widespread rainfall of 3 to 9 inches in the mountains area of Arizona and West-Central New Mexico during December 17-20, 1978, caused maximum known discharges on the Gila River in New Mexico and on several streams in Arizona. At Phoenix, the Salt River was the highest since 1920 but was only slightly higher than the flood in March 1978. The Agua Fria River was the highest since 1919. The floods caused 12 deaths and more than $150 million in damage. Damage of $51.8 million occurred in Maricopa County, Arizona. Ten counties in Arizona and three counties in New Mexico wer declared disaster areas. Unusually high volumes of runoff occurred on the Salt, Verde, and Agua Fria Rivers upstream from reservoirs. Overflow from the reservoir systems caused flooding downstream. Storage in the reservoirs on the Salt and Verde River reduced the peak discharge of the Salt River at Phoenix from a potential of about 234,000 cubic feet per second to 126,00 cubic feet per second and greatly reduced the duration of the flood. HYDROLOGIC DATA FOR URBAN STORM RUNOFF IN THE DENVER METROPOLITAN AREA, COLORADO,
Geological Survey, Lakewood, CO. Water Resources Div.
J. W. Gibb, and J. T. Doerfer.
Available from the OFSS, USGS, Lakewood CO 80225, Price: $77.50 in paper copy, $4.50 in microfiche. USGS Open-File Report 82-872, September 1982. 553 p, 3 Fig, 380 Tab, 9 Ref.

Descriptors: *Storm runoff, *Rainfall-runoff relationships, Rainfall-runoff modeling data, Water-quality data, Rainfall-runoff simulation data, *Hydrologic data, *Urban runoff, *Colorado, Denver Metropolitan area, Denver Regional Council of Governments, South Platte River.

Urban storm-runoff data collected from April through September 1981 from nine Denver Nationwide Urban Runoff Program sites, urban storm-runoff data collected from April 1980 through September 1981 from ten South Platte River Study sites, and rainfall-runoff simulation data from two sites for June 1980 and May 1981 are presented in this report. The Denver Nationwide Urban Runoff Program sites were two single-family residential areas, two multifamily residential areas, one commercial area (shopping center), one mixed commercial and multifamily residential area, one natural area (open space), and two detention ponds. The South Platte River Study sites were six tributaries of the South Platte River and four in-stream sites on the South Platte River. The tributary sites were Bear Creek at mouth, at Sheridan; Harvard Gulch at Harvard Park, at Denver; Sanderson Gulch at mouth, at Denver; Weir Gulch at mouth, at Denver; Lakewood Gulch at mouth, at Denver; and Cherry Creek at Denver. The in-stream sites were South Platte River at Littleton; South Platte River at Florida Avenue, at Denver; South Platte River at Denver; and South Platte River at 50th Avenue, at Denver. The rainfall-runoff simulation sites were North Avenue at Denver Federal Center, at Lakewood and Rooney Gulch at Rooney Ranch, near Morrison. Precipitation, rainfall-runoff, water-quality data, and basin characteristics were collected at the urban storm-runoff sites. The urban storm-runoff data may be used to characterize runoff loading for various land-use types in Denver and other semiarid regions. (USGS)

BASELINE WATER-QUALITY DATA FOR SAND-PLAIN AQUIFERS IN HUBBARD, MORRISON, OTTER TAIL, AND WADENA COUNTIES, MINNESOTA,
Geological Survey, St. Paul, MN. Water Resources Div.
C. F. Myette.
Available from the OFSS, USGS, Lakewood, CO 80225; Paper copy $14.25, Microfiche $3.50. USGS Open-File Report 82-909, October, 1982. 112 p, 2 Fig, 3 Tab, 5 Ref.

Descriptors: *Baseline studies, Water quality data, Sand aquifers, Hubbard County, Morrison County, Otter Tail County, Wadena County, *Minnesota, *Pollutant identification.

Tapping the surficial sand-plain aquifers in west-central Minnesota has raised the possibility for degradation of water quality. The sand-plain areas are generally overlain by sandy soils that permit rapid infiltration of precipitation and, possibly, of surface contaminants. One hundred twenty-five wells were sampled in Hubbard, Morrison, Otter Tail, and Wadena Counties during 1979-81 to establish regional baseline water quality. The wells were chosen to provide optimum areal coverage based on geology, direction of ground-water flow, and extent of aquifer development. Water from the sand-plain aquifers is of the calcium bicarbonate type. The water is hard to very hard with dissolved solids ranging from about 100 to 700 milligrams per liter. Locally, concentrations of dissolved solids, iron, manganese, and nitrate exceeded limits recommended by the Minnesota Pollution Control Agency. (USGS)

FLOODS OF DECEMBER 1982 AND JANUARY 1983 IN CENTRAL AND SOUTHERN MISSISSIPPI RIVER BASIN,
Geological Survey, Atlanta, GA. Water Resources Div.
V. B. Sauer, and J. M. Fulford.
USGS Open-File Report 83-213. 41 p, 14 Fig, 2 Tab, 10 Ref.

Descriptors: *Floods, *Flood data, *Regional floods, Flood hydrographs, Flood peak, Flood frequency, *Mississippi River Basin, Illinois, Missouri, Arkansas, Louisiana, Mississippi, Tennessee.

Widespread flooding occurred in December 1982, and January 1983, through a large part of the Central and Southern Mississippi River Basin. The States affected the most by these floods were Illinois, Missouri, Arkansas, Louisiana, Mississippi, and Tennessee. Two major storm periods occurred; one in early December and the other in late December. The early December storm resulted in outstanding floods mainly in Illinois, Missouri, and Arkansas. The late December storm produced major flooding mainly in Southeastern Arkansas, Louisiana, and Mississippi. Western Tennessee was on the fringes of both storms. Throughout the affected area for both storms, many streams exceeded previously known flood heights and discharges, and in many cases the recurrence interval of peak discharges exceeded 100 years. DISCHARGE DATA AT WATER-QUALITY MONITORING STATIONS IN ARKANSAS, 1980 WATER YEAR,
Geological Survey, Little Rock, AR. Water Resources Div.
R. K. Knott.
USGS Open-File Report 83-214, 1983. 36 p, 4 Tab.

Descriptors: *Streamflow, *Discharge measurement, *Arkansas, Water pollution control, Monitoring stations.

Discharge data were computed for a network of water-quality monitoring stations operated by the Arkansas Department of Pollution Control and Ecology (ADPC and E). All stations in the network were visited by Geological Survey personnel. Discharges on days of sampling were determined for 83 of the sites. A summary table of those discharges for the water year 1981 is given. Several discharges at three stations for miscellaneous dates in the 1980 water year are shown. Several discharges at four stations for miscellaneous dates in the 1979 year are shown. Several discharges at one station for miscellaneous dates in the 1978 water year are also shown. The letter-digit station numbers and names were devised and assigned by the ADPC and E. The corresponding eight-digit numbers are assigned downstream-order station numbers as used by the Geological Survey. (USGS)

Descriptors: *Water use, Irrigation water, Industrial water, Municipal water, *Estimated water use, *Florida, Southwest Florida Water Management District.

Water-use data for 1981 are summarized for 16 counties in the Southwest Florida Water Management District. Data include total use of groundwater and surface water for each of five water-use categories. The 1981 withdrawals for each category were as follows: 318 million gallons per day for public supply, 64 million gallons per day for rural, 314 million gallons per day for industrial, 595 million gallons per day for irrigation, and 7,680 million gallons per day for thermoelectric power generation of which 6,050 million gallons per day was saline water. ESTIMATED WATER USE IN MISSOURI, 1980,
Geological Survey, Rolla, MO. Water Resources Div.
M. Marikos, and J. Skelton.
Missouri Department of Natural Resources, Rolla, 1983. 1 Sheet Map, 14 Fig, 1 Tab, 7 Ref.

Descriptors: *Water use, *Consumptive use, Groundwater, Surface water, Irrigation, Industrial water use, *Maps, *Missouri, Public supply, Rural use, Thermoelectric use, Total use.

The map report summarizes 1980 water-use data for Missouri by counties for the following categories: public supply, rural (self-supplied), irrigation, thermoelectric, and industrial (self-supplied), irrigation, thermoelectric, and industrial (self-supplied). Total use during 1980 was about 6,345 million gallons per day. About 92.5% was withdrawn from surface-water sources and the rest from ground-water sources. Total water use increased by 81% during 1970-80, but population increased only about 5%. The major increase in use during 1970-80 was by thermoelectric powerplants, with small increases in public-supply withdrawals and irrigation. Rural and industrial use remained almost constant. (USGS)

CONSUMPTIVE USE OF FRESHWATER IN FLORIDA, 1980,
Geological Survey, Tallahassee, FL. Water Resources Div.
S. D. Leach.
Florida Department of Natural Resources, 1982. 1 Sheet Map, 7 Fig, 1 Tab, 5 Ref.

Descriptors: *Florida, *Water use, *Consumptive use, Freshwater, *Public supply, Rural water, Industrial water, Irrigation, Thermoelectric water use, Hydrology, *Maps.

Freshwater withdrawn in Florida for all uses averaged 7,309 million gallons per day (Mgal/d) in 1980. Of this amount, 4,831 Mgal/d was returned for reuse and 2,478 Mgal/d or one third of the freshwater withdrawn was consumed. The greatest use of freshwater was 2,997 Mgal/d prepared for irrigation, which had the greatest consumptive use of 1,547 Mgal/d, including an estimated 18 Mgal/d for conveyance loss. Consumptive use from irrigation was 62% of the total consumptive use statewide. Thermoelectric power generation, with an average withdrawal of 1,859 Mgal/d, was the second greatest user of freshwater, but had the least consumptive use of only 32.8 Mgal/d. The remaining consumptive use of freshwater amounted to 329 Mgal/d from public supplies, 102 Mgal/d from rural domestic and livestock use, and 467 Mgal/d from self-supplied industries. Consumptive use of water is a prime measure of the effect of water use upon the water budget in the State. As the total amount of freshwater withdrawn each year increases so will the amount of consumptive use. (USGS)

SGS Open-File Report 82-575, 1982. 298 p,
Tab, 26 Ref, 3 Append.

Descriptors: *Hydrologic data, *Tidal Potomac River, *Water quality, *Potomac estuary study, *Chlorophyll-a analysis.

This report contains data on the physical and chemical properties measured in the Tidal Potomac River and Estuary during the 1981 water year. Data were collected at least weekly at five stations, and periodically at 15 stations and at two other stations near the mouth of the Potomac River in Chesapeake Bay. Each of the five stations represent a cross section at which the transport of selected dissolved and suspended materials can be computed. The remaining 17 stations are locations at which data were collected for special studies of selected phenomena, such as salt water migration and dissolved oxygen dynamics. Samples were routinely analyzed for chlorophyll-a, nitrogen, pheophytin, phosphorus, silica and suspended sediment. Additional samples were analyzed for adenosine triphosphate, algal growth potential, alkalinity, calcium, chloride, dissolved-solids residue, fluoride, iron, manganese, magnesium, nitrifying bacteria, organic carbon, potassium, seston, sodium, and sulfate. In addition, in-situ measurements of dissolved oxygen, specific conductance, pH, temperature, solar radiation, and secchi disk transparency were made. (USGS)

WATER QUALITY MONITORING - RIVERS AND STREAMS, 1982.
Indiana State Board of Health, Indianapolis. Div. of Water Pollution Control.
Report, 1982. 138 p, 6 Tab.

Descriptors: *Water sampling, *Water analysis, *Water measurement, Water pollution, *Water pollution control, *Water pollution effects, Water quality management, Water quality, Biological samples, Chemical analysis, Chemical composition, State jurisdiction, Municipal water, *Indiana.

A program in Indiana to provide basic information on pollution trends and to provide water quality data for the state's surface water users has been described in annual water quality reports. This report, the 25th, emphasizes the importance of surface water via the fact that two-thirds of the water usage in Indiana in 1980 was obtained from surface supplies. While 49 sites were sampled in 1952, 92 stations are included in the current program. Physical, chemical, and bacteriological analyses are made on samples collected from all 92 stations; plankton analyses from 18; and radiological analyses from 23. The forty-five methods of analyses used represent the minimum of bacteriological, chemical, and radiological analysis which would justify the collection program. The monitoring program is intended to indicate, when possible, the sources of pollution abatement programs, and to collect background data on certain types of waste, such as chlorides and radioactive materials. The monitoring stations are selected on the basis of having waters used for municipal, industrial, agricultural and recreational purposes; if they are near known or suspected sources of pollution; and when they are near state boundaries to determine the quality of water entering or leaving the state. Routine samples include 2,000 milliliters for chemical analysis and about 100 milliliters in a sterile bottle for bacteriological analysis. This year no flow data are included. (Garrison-Omniplan)

WATER-LEVEL MAPS OF THE ALLUVIAL AQUIFER, NORTHWESTERN MISSISSIPPI SEPTEMBER 1981,
Geological Survey, Jackson, MS. Water Resources Div.
D. Darden.
USGS Open-File Report 82-574, 1982. 1 Sheet map, 1 Fig, 6 Ref.

Descriptors: *Mississippi, *Groundwater, *Aquifers, *Water levels, Mississippi River valley alluvial aquifer, Quarternary aquifers, *Maps, Water wells.

Water levels were measured in 427 wells in the Mississippi River valley alluvial aquifer in northwestern Mississippi during the period September 15-28, 1981. Water levels in the alluvial sands and gravel were generally lower than water levels in September 1980 and larger depressions in the surface of the ground-water body were detected in the Sunflower-Leflore County area and in Humphreys County. These depressions are attributed to heavy pumping for irrigation and to less-than normal rainfall. Other smaller depressions are attributed to local heavy pumping. (USGS)

MONTHLY LOW-FLOW CHARACTERISTICS OF GEORGIA STREAMS,
Geological Survey, Doraville, GA. Water Resources Div.
R. F. Carter, and J. D. Lewis.
USGS Open-File Report 82-560, 1982. 81 p, 6 Fig, 1 Tab, 12 Ref.

Descriptors: *Flow variability, *Low flow, *Monthly frequency, Time sampling, *Streamflow, *Stream gages, *Georgia.

Statistics of monthly minimum flows are presented for 129 streamflow stations for each month of the year. Flow statistics provided are the log-Pearson Type III distribution. The probable magnitude of average standard errors due to time-sampling bias is tabulated. The average standard errors were found to be similar over a wide area comprising approximately the northern two-thirds of the State. In this area, the average standard error of estimate for a low-flow statistic with a recurrence interval of 20 years and estimated on the basis of 10 years of record is about 17%. In the southern third of the State, the average standard errors were found to lie in a narrow range, but were significantly greater than in the north. In the southern area, the average standard error of estimate for a low flow statistic with a recurrence interval of 20 years and estimated on the basis of 10 years of record is about 40%. (USGS)

WATER QUALITY OF COAL DEPOSITS AND ABANDONED MINES, SAGINAW COUNTY, MICHIGAN,
Geological Survey, Lansing, MI. Water Resources Div.
A. H. Handy.
USGS Open-File Report 82-511, 1982. 35 p, 7 Fig, 5 Tab, 12 Ref.

Descriptors: Water quality, *Groundwater, Streams, Wetlands, Trace elements, *Coal mines,

Mining, Glacial drift, Saginaw formation, St. Charles, Saginaw County, *Michigan.

Coal was last mined in Saginaw County, Michigan in 1950. Water from abandoned mines and from undisturbed coal-bearing beds in the Saginaw Formation is highly mineralized and contains high concentrations of iron. Compared to streams in the area, the water contains higher concentrations of at least 15 constituents including boron, phenol, lithium, strontium, and manganese. Water from abandoned mines and coal-bearing beds is a poor source of water for domestic, public, or agricultural uses. Large amounts of this highly mineralized ground water reaching local streams would have a deleterious effect on surface-water quality. (USGS)

DATA FOR GROUND-WATER TEST HOLE NEAR ZAMORA, CENTRAL VALLEY AQUIFER PROJECT, CALIFORNIA,
Geological Survey, Sacramento, CA. Water Resources Div.
J. J. French, R. W. Page, and G. L. Bertoldi.
Available from the USGS, OFSS, Lakewood, CO 80225, Price: $12.25 in paper copy, $4.00 in microfiche. USGS Open-File Report 82-510, July, 1982. 72 p, 13 Tab, 16 Fig, 22 Ref.

Descriptors: Test holes, Electrical well logging, Radioactive well logging, Diatoms, Clay minerals, Piezometers, *Water level fluctuations, *Water quality, *Groundwater, Sacramento Valley, *California, Yolo County, Central Valley Aquifer Project.

Preliminary data are presented for the first of seven test holes drilled as a part of the Central Valley Aquifer Project which is part of the National Regional Aquifer Systems Analysis Program. The test hole was drilled in the SW 1/4 SE 1/4 sec. 34, T. 12 N., R. 1 E., Yolo County, California, about 3 miles northeast of the town of Zamora. Drilled to a depth of 2,500 feet below land surface, the hole is cased to a depth of 190 feet and equipped with three piezometer tubes to depths of 947, 1,401, and 2,125 feet. A 5-foot well screen is at the bottom of each piezometer. Eighteen cores and 68 sidewall cores were recovered. Laboratory tests were made for mineralogy, hydraulic conductivity, porosity, consolidation, grain-size distribution, Atterberg limits, X-ray diffraction, diatom identification, thermal conductivity, and chemical analysis of water. Geophysical and thermal gradient logs were made. The hole is sampled periodically for chemical analysis and measured for water level in the three tapped zones. This report presents methods used to obtain field samples, laboratory procedures, and the data obtained. (USGS)
